We finally got some ROMS and we had four machines that we had upgraded to 1 Meg. Here is a set of experiences that may help some people that may run in the same problems that we did.

All the machines were running fine with the upgrade and without the resistors. I put all 6 68 O (O == ohms) resistors in, and it worked fine with the Roms and all.

Now we went to do my office mate's machine. We put the 68 O resistors, no roms and the machine recognized the upper 512K, but we started getting random errors (looked like the rams we not holding data). So we took one resistor out of the pin 4 (RAS) bus of the upper 512K and hooked the bus directly to the MM chip. Worked fine (the 68 O resistors were in on the 2 pin 15 (CAS) busses of the upper 512K). The lower 512 K was doing just fine with all the resistors in. The only difference between between this machine and mine was that I had Hitachi chips and this machine had Oki chips. So we guessed that they had different operating points, and so we tried a lower value resistor, 39 O on the pin 4 (RAS) bus. This time we started getting consistent errors (every alternate address above 512K read FE instead of FF). So we went for a even lower value resistor, 27 O, and then everything worked out just fine. Now we have the Rom in, and its doing just fine. Has anyone else come across such problems??

We mounted our resistors on a little piece of PCB and stuck it to the left of the Rams, and ran wires from the MM chip to the appropriate spots (after cutting the 3 lines (RAS and the two CAS's of the lower 512K), instead of soldering the resistors to the traces or the memory chip directly.

OK, looks like I am on through the Atari VAX now. So let me introduce
myself.

Name: Neil Harris Title: Director of Communications
Marketing Dept. Atari Corp.

I make sure we are letting everyone know what we are up to. I do this via our magazine, "Atari Explorer", our dealer newsletter, and on every online service I can find including CompuServe, BIX, the WELL, GENIE, and the official Atari BBS (408-745-5308, 4 lines, no waiting!).

If you have serious technical questions they should probably go through Landon Dyer who has already checked in here (yes, he's the one on the BIOS listing). I can help with many technical matters and with most product availability questions - I was an applications programmer in a previous life. If I do anything silly here it is because I'm a beginner at UNIX -- have been playing with itty bitty computers for too long.

Some interesting news: the first shipment of 1040ST computers has arrived in the Atari warehouse, according to Sam Tramiel (our President). We also got the first batch of 520's with TOR in ROM and with modulators.

Keywords: three weeks
Summary:

The latest thing I've heard is that there hasn't been a single 1040 sent over from Japan yet. When they do get here (about a week, I was told), they'll probably spend a week in Atari's QA department for testing and then be shipped. There will be only 4 (!) distributors for 1040s in the US. So the bottom line from my dealer is that it will be about three more weeks before I see my 1040. *sigh*

I'm going to be purchasing a modem for my Atari 800 and need some info on what to get. I definately want the kind that connects to the SIO port, no 850 interface needed, and I would perfer a 1200 BAUD unit to a 300 BAUD.

The two I'm most interested in are the Supra MPP1200AT which is Hayes command compatible for about $189, and the Digital Devices Pocket Modem which is available both as a 1200 BAUD unit and a 300 BAUD which can be upgraded to 1200.

I have some manufacturers literature on both of these but that's all advertising. Anyone ever use either of these? Or have experience with any other brands that you would recommend? Any information would be appreciated.

Kevin Thompson {ucbvax,ihnp4!nsc}!voder!kevin

I have made the expansion with no resistors and no problems. The schematic
I got with the developer's package shows no resistors in RAS or CAS for the
original chips either.

Can do. Since I am not a systems programmer, there are some questions I

won't know the answers to right away -- but I have access to those who do. And, of course, I have the availability info that seems to have been lacking here.

Speaking of which, as stated in my last message -- the 1040ST shipment has definitely arrived in the US warehouse and should be going out to dealers shortly. Dealers who buy through distributors should call to find out which distributors carry the 1040's, all others should call their rep or Atari direct.

Atari Bonanza, a mail order program from Atari Corp., is selling the touch tablets direct from the Atari warehouse. The price is $44.99. Send to:

Atari Bonanza, Dept. X3
PO Box 3427
Sunnyvale, CA 94088

Please allow 6 to 8 weeks for delivery. Price includes shipping & handling.
California residents add 6.5% sales tax.

I think that I should apologise to the (Atari) world in general, and
Mr Weisman in particular, about my snide comments on spelling and grammar.
For once, irritation overrode good sense. In fact, I have seen worse
examples of misspelt words and gramatically incorrect sentences elsewhere.
A philosophical discussion on whether the meaning of a message is more
important than the presentation should move to another group (net.junk?).

Since this is Atari, a question relative to the 1040ST. I see comments
that it is being released in Europe, but have not yet seen references
to it in the European Atari (or general PC) journals. Is the 1040ST
really being released in Europe, or is it simply a smokescreen to hide the
fact that it does not yet exist?

Caesar (or Reagan?) non supra grammaticos.

*** ***

   Since we now have an official source for Atari news here on USENET,
could we get beyond the rumors of what the 1040ST actually is?
What I've gathered is that it will be 100% compatible with 520 software,
have 1 meg of RAM, TOS on ROM, a double sided drive, a list price of
$200 more than the 520, and come nicely packaged in a single box. Is
that correct? Any additions?
   About TOS in ROM... a friend has a 520ST, and would like to know how
one goes about getting the ROM chips. Should they be available from
dealers, or do you have to go directly to Atari?

 - Joel ({allegra,ihnp4,seismo}!uwvax!uwmacc!oyster)

P.S. Jim at Nicolet-- you've got a customer for your first 1040ST. I'd be
interested in hearing what you know about availability.

Does anybody know how to use the new EPSON LQ800 (24 pin) with
the 520ST in graphics mode (like a screen dump from the OS).
THe LQ800 works fine in text mode, but I get nothing but garbage
when I try to send graphics. The basic problem is that the 24
wire head needs 3 times the information. I know that there is a way
to default the LQ800 to regular FX80 graphics codes but I haven't
figured out how yet. I have tried sending ESC L and ESC Y befor the
dump but this didn't work. I have called EPSON but they don't
seem to know either. How do I know that this is possible? I have
seen it done at a store, but since I didn't buy the ST at this particular
store, they weren't willing to tell me how to do it. Also,
my phone numbers for Atari don't seem to work any more.
Does anyone have a phone number that actually gets answered.
(tape recorders don't count)

Thanks
R.T. Bradstrum

I have been trying to download some files from a Un*x machine
and apparently what arrives doesn't have carriage returns. Can
anyone send me a program to convert from Un*x to ST text format,
either to run on the ST or the host?

Thanks in advance

Bart Atwell

The last time I asked Richard Frick when a Font Editor/Loader would be
available for the ST, he said 'maybe never.' Has this changed? Does the
VDI load_font routine work, or is yet another of the VDI functions that DRI
hasn't gotten around to implementing?

Also, I've been trying to figure out how to scale down the system font to a
smaller size. I've been able to use vst_height() call to increase the
character size, but every time i try to shrink it I get mushrooms. How does
one get the small font that Icons are labeled with and the Doodle prog uses?

=-=
No problem is so formidable that you can't just walk away from it.

Now that Atari's on-line, I have a few (loaded) questions:

Will Atari be releasing an SCSI expansion option for the ST (Giving us
more and immediate expansion options including laser printers, shared
disk drives, CD-ROMs, WORMs, plotters, free networking, ethernet...)?

Is the 8 "slot" expansion 8 SCSI ports (giving 64 possible devices),
1 SCSI "circuit" with 8 connectors, or 8 "Proprietary DMA (yecch)" ports?

Will/Do the Atari hard disks have SCSI in/out ports for daisy chaining
devices?

What kind of "Boot" is required for the SCSI (or SASI) port?

Will there be any sort of internal RAM expansion pins (molex type?)
on the 1040 or Rev B or C 520 machines?

Are the CPU's socketed on the new machines?

Will TOS in ROM support a 68010?

VDI and AES are re-entrant right? What about BIOS and XBIOS?

Any plans on adding full pre-emptive multi-tasking (running N applications
at once so that Paint can print while the user Draws another document)?

Any effort being made to keep software products from "stepping on each other"?

Are 'hooks' available for 1 meg chip expansion (18 pin sockets, sips...)?

Any plans for a real MMU replacement for the memory controller chip?

Which of these are reserved for the TT machines?

When are the TT machines coming?

Is high res 70hz really non-interlaced? If so, why jump to 70hz (and
eat bus bandwidth)? It's a beautiful display, so it doesn't really matter
whether it is or not, but I have a Ball monitor that only goes up to 21Khz
horizontal, can it be used?.

By the way, just looked at the 'ST Internals' manual from Abacus, the
improvements of TOS over CP/M are great, especially the 'C' compatibility.
Ya Done Gud :-)

These have been hot issues on the net for some time now, and it would
be nice to get some official answers.

Also, thanks for making TOS in ROM a bit "flexible", in case multi-tasking,
better version "patches", or new features become available, it appears
to be a good compromise (Get almost all the RAM, and upgrade flexibility).

As part of Engineers' Week, the UCLA Student Chapters of the ACM and
the IEEE will be hosting the UCLA Microcomputer Faire 1986. To be held
in the John Wooden Center on Wednesday, April 16th, the Faire provides
both access to a large group of interested students, faculty, and staff,
as well as exposure to the future users and purchasers of microcomputer
systems and components. At the present time, the Microcomputer Faire
Organizing Committee is in the process of inviting companies that have
products in the following areas:

1. Complete Systems:
   -Hardware and Software

2. Hardware Systems:
   -Processors, etc.

3. Software Systems:
   -Operating Systems
   -Development Environments

4. Hardware Peripherals:
   -Printers, plotters, hard copy devices
   -Modems, communication devices

-Boards, cards, expansions units
-Disk drives, tape drives, secondary storage
-Mouses, tablets, digitizers
-Monitors, displays
-Miscellaneous

5. Software Packages:
-Games
-Languages
-Data bases
-Graphics
-Word Processing
-Text Formatting
-AI
-Engineering: CAD/CAE, simulation, etc.
-Spreadsheets (?)
-Business Applications
-Scientific
-Networking
-Miscellaneous

6. Microcomputer Magazines:
-End user oriented
-Industry magazines and newsletters (?)

7. Advanced Technologies:
-Optical CD ROM
-AI
-Networking (LAN's, micro-mainframe, etc)
-Distributed Architechtures
-RISC
-MISC

8. Miscellaneous:
-Miscellaneous

If there are any companies doing business in these areas that you think might benefit by attending the UCLA Microcomputer Faire and can show off their products to the next generation of computer system purchasers, we would appreciate it if you could send to us the name of the company, a representative's name and phone number, and the product(s) that they would like to demonstrate. (Such as those related to the Atari 520 ST and the Atari 1040...) As well, we would be most grateful if you could show this to friends or acquaintances that are involved with microcomputers to ask for suggestions.

Thank you,

David Lee
Microcomputer Faire Chairman

VOICE: (213) 825-7597

p.s. In previous years, we have only invited companies that manufactured
general purpose systems and had audiences of 2000 in THREE hours.
This year, with the expansion of the Faire to accomodate more
companies, a registration fee of $100 will be charged to each
company in attendance and the Faire will be 5 hours in length.
Also, light breakfast, refreshments, a reception with deans and
professors, and possibly lunch will be available to the company
representatives.

Neil,

Maybe one of the questions you could answer for us is: What is your pathname
and can we send you mail?

I have looked over the newsite info but can not find out to which machine(s)
you are connected. Can you or anyone else help out?

Thanks!

i was in fact looking forward to the 520 coming out in kmart stores.
this would mean lower prices for good equipment. i was however diswturbed
when i heard rumors that the atari/kmart deal was falling through...
can anyone confirm this?

If you want the lower level features with a language very similar to
Pascal, I recommend the TDI Modula 2 compiler. The documentation is
superb and has many examples for using the GEM operating system. In
fact, even if I was going to do everything in C, the manual would be
a significant help in deciphering the developers kit manuals. I have
been using it currently with one double sided drive(my other drive is
in the shop) and can compile/link a reasonbly sized graphics program
in about 3.5 minutes. The package has all of the bindings necessary
to talk to GEM. The language allows address manipulation as well as
inline machine code(hex codes, not mnemonics).

For the $60-$70 price tag, its well worth the price.

Is the touch tablet the keypad-like thing that is used with some versions of Star Raiders on the video game machines? I bought two copies of Star Raiders for a game machine I do not own because they contained these keypads and were selling for $1.99 each on a closeout. I think it was at Child World or Toyland or some such place in Chestnut Hill Mall here in the Boston area. I figured that the joystick port connector alone was worth that much, and I was getting a keypad and a ROM containing the code for Star Raiders "to boot" (so to speak). (Does anybody need Star Raiders for a 2600?)

If you can determine that this is the gadget you want, I would be amenable to dropping by this store to see if they still have any more of the gadgets, and I MIGHT be induced to part with one of the two I got in December, if additional copies are not available.

Oh, by the way, you also get an "Atari Force" comic book for your $1.99!

It was pointed out weeks ago on the net that the 520ST at K-Mart will not be a reduced-price version but rather an un-bundled version. At $300 for just the keyboard/CPU console, you'll be up to $700 or $800 if you add a disk and a TV set or monitor. Of course, the move to K-Mart might signal the start of price wars that will eventually bring the price down.

Have any of you hackers out there figured out how to access CPM/68K without
buying the $300 "developers' kit"? According to COMPUTE! Magazine, the
GEM desktop is "really" built on top of CPM and can be "peeled away" if you
know how. It seems that getting rid of GEM should cost negative, not positive
dollars! Has anybody figured out how to do this?

(I dunno why I care - I haven't bought my ST yet!!!)

> dealers, or do you have to go directly to Atari?

The 1040ST also has a built-in power supply for both the computer and the
drive. It looks like a 520 except for a couple of extra inches in the back
of the system Otherwise, exactly as described above. Look for the next
issue of Byte (March 1986) to have a full preview of the 1040ST.

The ROM chips are available from dealers. Suggested price is $25. If
your dealer does not know about them, tell the dealer to call Atari's
service dept.

I just read in the March issue of Analog that the OS/9 operating
system *is* being adapted to run on the ST. They didn't mention
the name of the company though. Also they reinforce my opinion
that almost all of the software HIPPO puts out is rushed and that
you should check out your other options before buying their inferior
software :-)> (This opinion doesn't apply to their hardware, as I
have no information on it).

First, I'd like to know how many chips in the ST are
soldered in instead of socketed, and which these are.
Please answer this for the early STs, the current models,
and the future shipments. I'd like to decide which
vintage model would be best for doing hardware upgrades
(piggy back RAM, 68010, etc).

More serious: How can the ST be bus-expanded?
The *other* brand brings its entire bus to the side connector,
but the ST has only a read-only 128K game cart socket
(what, games? on an Atari??). How can there be an
expansion chassis into which we can plug boards with
lotsa RAM, 32000 co-procs, or whatever else needs some
direct bus access? Will we be stuck with a box hung
off the floppy or hard disk serial ports?
Which can't be accessed directly?

Tecmar is already advertising a true expansion box
for the you-know-what.

Finally: Is it possible to write directly to the graphics
bitmap in RAM (from an assembler or C program)?
Where speed is of the utmost, we'll need to be able
to do our own custom bit-blits, quickdraws, etc.
to compete with the custom graphics chips in the
high-priced machine.
I heard that on one of the machines (forget which)
you were somehow prevented from direct access to the
graphics area (this may just be a BASIC restriction,
as there is no MMU in either machine to stop machine
code routines from doing it).

Hoping to get an ST soon, mike k

Someone asked whether an ordinary monochrome monitor
could be tweaked up to run on the ST.
In color modes, yes (with some interface work).
But for the 640x400, nope!
I took a closer look at the pretty colored Atari flyer
spec sheet, and not only is the vertical frequency
up to 71 Hz, but the Horizontal is a whopping
35.7 KHz, or 2.13 times the NTSC standard 15.75!

This answers a long-standing question--
ST Monochrome is NON-INTERLACED!
It really draws all 400 lines in each of 70 frames/sec!
Atari really went all the way on this.

Maybe the IBM PC monitors are already up there

(I think the Mac is only 22 KHz or so),
but no 15.75 KHz monitor could be tweaked to over
double its design freq.

     mike k

PS: This assumes that the spec sheet is correct.
PPS: The sheet also sez the RGB uses separate,
not green, Sync.

In a reply to a recent query about disk densities, Rob Botwin said
that the PERCOM density command format was copied by everyone including
Atari. Sorry to say, from what I understand, Atari is the ONLY company
making disk drives for the Atari which does NOT follow this standard.

This is definately true for the 810. I cannot vouch for the 1050, but
as far as I know it also is 'dumb' as far as density settings. It can
read single density format disks, but unless upgraded, it cannot read
or write true double density. Nor can you use the PERCOM commands to
ask it it's current density or reset it.

I assume that the "read the first sector" method that David suggested
was meant for 1050 disk drives. (NOTE: David Young, (sorry)).

If I am misteaken in any of these statements or beliefs, please someone,
correct me.

>Have any of you hackers out there figured out how to access CPM/68K without

>buying the $300 "developers' kit"? According to COMPUTE] Magazine, the

>GEM desktop is "really" built on top of CPM and can be "peeled away" if you

>know how. It seems that getting rid of GEM should cost negative, not positive

>dollars] Has anybody figured out how to do this?

PLEASE John]]]: The 520 ST is NOT using CPM/68K. It is using TOS

(Tramiels Operating System). By using the program COMMAND, you enter

the TOS which LOOKS LIKE an CPM environment, but it isn't.

ATARI wanted to use CPM/68K but it was far to slow so they wrote their

own OS. TOS is more like UNIX. So you CAN NOT run CPM/68K programs on

the ST without making some software interfacing. Anyway, COMMAND comes

with the "developers' kit". Maybe there is also a public domain version

around. Does anyone know?

The developer's kit has a version of Kermit in it, but it is not clear to me whether this program can be freely distributed. The Kermit documentation Atari includes comes from Columbia, and the Kermits you get from Columbia can be distributed as long as it is not for profit. [It looks a bit like one of their older Unix Kermit programs]. Now that Atari is on the net, perhaps they can comment on whether we are free to distribute this program.

In the revision B board, all of the chips are soldered except for the custom chips (Memory Manager, Glue, Video). This probably will not change in the future, except that the custom chips might also get soldered in also.

I have done the ram upgrade on my board with no problems. I have also
talked with several people who have done the upgrade on newer machines
with no problem. Get the latest vintage machine you can.

The floppy disk and hard disk ports are parallel ports, NOT serial ports.
The hard disk port is really a general purpose DMA port for the Atari.
This port, with some massaging, can be made to look like a SASI or SCSI port.
This, of course, takes a little extra hardware on a PC board. The Atari
hard disk is a disk connected to the extra hardware which is
then connected to the Atari. The hard disk thinks it is talking SASI (or
SCSI, I can't remember at the moment). Presumably, one could build an
expansion cabinet using this method of communicating. It isn't as good
as a full bus expander, but it can be very useful.

There IS a primitive MMU in the Atari that will prevent access to certain
areas of memory if you are not executing in 'supervisor' mode. And yes, it
is possible to write directly to the bitmap RAM. You won't need to write your
own bit-blits, quickdraws, etc. because they are already provided in the
line-A interface in the ROM of the Atari. This code is what the low-level
routines in GEM and VDI end up calling. If you wish to bypass GEM to get
ultimate speed, all you need to do is use these routines.
> Hoping to get an ST soon, mike k

I hope you do too. Order a development kit also, it will be worth the time
it takes to delve through all of the crud to get the juicy parts. Atari and
Digital Research are introducing a new version of the kit within a month that
is supposed to have many bug fixes and a total (and much needed!)
reorganization of the documentation. You should probably wait until that

comes out to buy one.

Good Luck.

A year or two ago there was an ad in some magazine about an input device to the Atari 400 and 800 computers which was wrapped around the heade like a headband. Does anyone have any information about this? Are they still being made? How do they work?
Thanks.

In article <1436@gitpyr.UUCP> tynor@gitpyr.UUCP (Steve Tynor) writes:
>Does the
>VDI load_font routine work, or is yet another of the VDI functions that DRI
>hasn't gotten around to implementing?

Digital Research is not responsible for writing Atari's VDIs. If there are any unimplemented functions, talk to Atari. Also, the VDI specification allows for functional subsets. These limitations can usually be found in the return from the Open Workstation call, the Extended Inquire function, and the other Inquire Functions.

To answer your question though, Load Fonts is implemented. The reason it is so difficult to create a font is due to the odd format fonts are required to use. But I can't believe that no one will come out with a font editor! Didn't I see one in ANTIC a while back?
>

>
The system font can not be scaled down; in fact, no font can be. They can,
however, be doubled in size, but that's it. Please send the code that
creates the Unhandled Exception (aka mushrooms) so that I can see why it's
failing. I'm working on a new set of VDIs now, and I'd really like to know
why this happens.

     While using PC/Intercom (V 3.03) sometime back, I noticed that
if the program freezes, all you have to do is hit the UNDO key and when
it asks, "Do you really wish to exit?", type "n" (so that it does not
exit). This usually fixes the problem and rebooting is not required. If
the problem is really severe, you may also need to choose the reset
option from the menu (after you have unlocked the program by hitting
the UNDO key etc.).

     Also, I noticed that the copy-protection on this program makes

the drive go to track 2 or whatever and the drive makes a really scary noise (at least mine does). Is this like the infamous destructive "head-banging" that the C64's drives are made to do? I would appreciate a comment on this from someone who knows what the inside of the 31/2 inch drive is like and what it does when it makes that grating noise. (This noise has tempted me to "fix" the code...)

In all the ST's that I have seen, Only the Glue, MMU, Roms and Dma chip are socketed. The rest are soldered. Having participated in 4 piggy back memory upgrades, I don't see how socketed memory chips would help. It would help ofcourse in replacing chips, but then the socket may be put in at that time.

> More serious: How can the ST be bus-expanded?
> The *other* brand brings its entire bus to the side connector,

> for the you-know-what.

Well it depends on how you look at it, if you really need a bus coming out to the edge. If you do a co-processor box with its own backplane etc, then all you need the ST for is to do I/o for you. Further, a hard disk could be used directly without the need for going through the ST. So now you would need the St for graphics,Screen/Kbd i/o, floppy and for access to the various ports. If you do the interface right, the 10 Mhz DMA port is plenty fast. I know of two such boxes, the TT (apparently it will be announced at the Hanover Fair next month) and the $199 Ibm Pc compatible 8088 box. Most people who critisize the St for not having expansion slots fail to point out how many of the ports that normally sit on expansion cards on things like the Ibm Pc are built in. Further, a lot of people seem to have the misconception that a particular hardware subsystem has to sit on processors/backplane bus for efficiency. If the functinal partitioning is done correctly (ie. you dont need to get at every signal of the processor/backplane bus, but just need to pass data fast between the two subsystems, and the minimum amount of control or state info that you can get away with) then i claim that the Dma approach is superior (No electrical loads, simpler control, clean interface beween subsystems, no bus - are some of the reasons that i come to mind). I am not totally convinced that a backplane is required. But then I may be totally wrong. Can anyone convince me otherwise?

(BTW for the price that Tecmar is charging for the expansion box i can have 3 1/2 St's sitting on my desk!!)

     yes you can write directly to screen memory. In fact you can designate any 32K chunk of memory on a 256 word boundary to be the screen memory (gets switched at the next Vblank). In the V blanking period the screen memory/ pallette can be manupulated to get interesting effects. It is also possible to dynamically link in your own handlers for the blanking interrupts.

GTE or AT&T had an ad offering a deal for $25.00 that would permit
almost unlimited connect to bboards throughout the nation at other that
peak hours. Does anyone know anything about who to call (numbers).

Also, are there public domain archives for software available on the
net?

Thanks in advance for any assistance provided.

Since there have been two notes expressing disbelief of the "read the
first sector" method to switch drive densities, I feel that I must
respond. How do you think that a drive knows which density to use
beyond sector 3 when it boots a double density drive? I admit I am a little
fuzzy on the matter since it has been a good while since I thought about
it, but I believe that the first byte of the first sector is the flag
that the drive is looking for. I have both a Percom and an ATR8000 and
I know that if the drive is not at the right density to read the disk
that I have just stuck in the drive I can use OMNIMON to read sector 1
and I am then free to read any other sector on the disk.

To redirect to the printer:

```
batch c prog >PRN:
```

```
          ^
          Note that there is no space.
```

The stdio routine gets(and therefore scanf) requires a CTL-J to terminate
the line. This is an acknowledged bug and is supposed to be fixed in the
next software release. You can use the BDOS read string command to come
close to a gets. The documentation is in error in that the returned
string is NOT null terminated. If you are interested, I can send you
a short routine which emulates gets quite effectively.

While I don't have an ST, you may want to check what the value of a
carriage return is on the ST, then use the UNIX 'tr' command to translate
a UNIX CR ('^J' or 012 octal) to the ST CR (lets say it's '^M' or 015 octal).
So on UNIX issue the command:

    tr "\012" "\015" <Unix_file >ST_file

this will change the '^J' to '^M' in the Unix_file and put the result in the
ST_file, which can then be downloaded. This is what I do to download UNIX
files to my Atari 8-bitter (CR=233 octal).

Agh, what does COMPUTE! magazine know about anything? The GEM Desktop (and

GEM in general) is NOT built on CP/M-68K. CP/M-68K doesn't support sub-directories (aka folders), so we wrote a new operating system called GEMDOS (renamed by Atari to TOS) that supported subdirectories and an MS-DOS compatible file system.

You can peel GEM away if you really want; you won't have any means of talking to GEMDOS then. What you want is the command line interpreter, which uses that familiar old {A} prompt. And that comes with the developer's kit. However, Dr. Dobbs has been publishing a command line interpreter for the PC; somebody could merely adapt this for the ST and make it public domain.

One of the annoying things about UNIX (compared to SENSIBLE operating
systems) is that "line feed" is the end of line marker. Your best
bet is to write a filter under UNIX to replace '\n' with "\0x0d\n" in
the file you are downloading.

Not public domain, but how about $50 for a pretty complete C-Shell?
David Beckmayer sells Micro C-Shell for the 520ST, and, though I haven't
received my copy yet, Art Leyenberger of Analog Magazine claims it's great.
The $50 version comes with various development tools, and I think there's
a $25 version which is just the shell itself.

David's address:

Beckmeyer Development Tools
592 Jean Street #304
Oakland, CA 94610

He has also mentioned on CompuServe that he has a *multitasking* kernel
for the ST called Micro-RTX, and will send the specifications to those
interested. Not sure if he's shipping it yet. This kernel is for
development on the ST only, and is not designed as a general multitasking
environment.

Hope my facts are right...

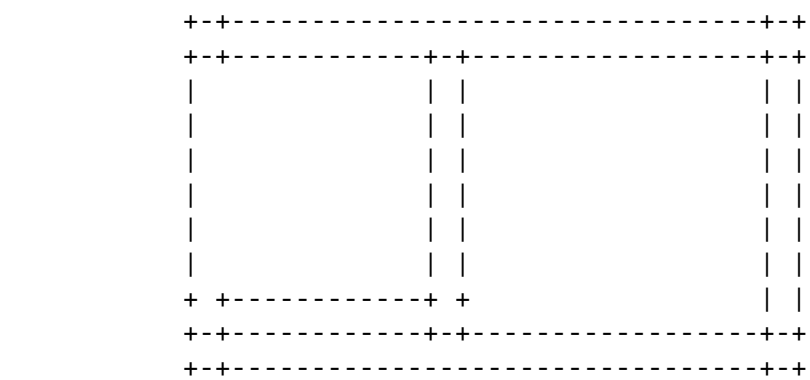
Attention Atari and/or DRI:

GEM AES Help Needed!

I'm trying to write code to support a two paned window by creating two windows with one fixed in the left side of the workspace of the larger one like this:



The large window is a complete window, with SIZER, MOVER, SCROLL-BARs, CLOSER, etc. the SUB-window has only SIZER and SCROLL-BARs. the SUB-window is fixed in position with respect to the large window (ie. when the large window is moved, the sub window moves with it...)

The problem centers on the fact that only one window can be active at a time. Thus, in order to detect SIZE-EVENT from both windows, I add the MOUSE-EVENT to the EVENT-FLAGs. Thus when I enter the

rectangle defined by the SUB-WINDOW, I TOP the SUB-window, when I exit that rectangle, I TOP the large window.

Here are the problems:

  1) when the mouse enters or exits the event rectangle, the large window's borders are redrawn, but the SUB-window's borders never are... Why? This has the effect of making both windows look 'active' when only the large one is, but when the SUB-window is the active one, only it looks active...

  1.5) It's pretty annoying to see the large window pop in and out of its 'active' state just because the mouse happens to move through the SUB-window. Is there a way to fool the AES into making 2 windows active concurrently?

  2) When trying to RESIZE the SUB-window to larger than current size, the EVENTMULTI catches the MOUSE1EVENT (and my window handler puts the large window on TOP) before it catches the RESIZE EVENT. The RESIZE EVENT is ignored! I don't think it is ever getting recieved by my application.

How do you suggest I do what I need to do? Expert advice from ATARI or DRI would be much appreciated...

ADD A COLD START RESET TO YOUR XE

After I got my new 130XE, I began to get a little frustrated by the ram chips in it. In order to do a cold start, I had to leave the machine off for at least 20 seconds. This is a *real* long time.

I was convinced there had to be a better way.

First of all a little history about what causes the problem. When Atari switched to the XL/XE line of computers, they changed the reset button to do a hard chip reset instead of an interrupt like on the old 800's. This means that every time the reset button is pressed the 6502 does a reset and starts over. The software must determine whether this is a cold start (power up) or a warm start (reset button). It does this by checking for a signature in the ram. On the XE there are three bytes $33D, $33E, $33F. If these three bytes are intact ($5C $93 $25) then it does a warm start. If any of them are wrong then it does a cold start.

The same day that I picked up my 130XE, I ordered the OMNIVIEW XE operating system from CDY. This OS gives you several advantages.

1. It does away with the need for a translator disk. It looks like the old Rev B operating system.
2. It gives me an 80 column mode for some applications.
3. It reverses the effect of the option key at coldstart.
4. It gives me ramdisk capability with any DOS.

This OS only uses the first byte of the signature ($33D).

I decided to fix my OMNIVIEW XE OS first.

You will need access to an EPROM burner and a 27128 EPROM to make this fix.

The fix.....

My fix involves 'stealing' the reset vector and checking the keyboard secondary buffer. This is a byte at $2F2 where the keyboard handler keeps the last button press to see if it should start auto-repeating on the next key stroke. I decided to use 'shift esc reset' as my cold start method. If the byte at $2F2 is $5C then the last key press was the 'shift esc' and I trash the byte at $33D and let the system continue with a normal reset. This will cause a COLD START without touching the power switch.

The program.....

```
LDA $2F2   load the last key buffer
CMP #$5C   check it for 'shift esc'
BNE EXIT   branch if it isn't
LDA #$00   load a zero
STA $033D  trash the signature
```

EXIT JMP RESET continue with the system reset vectors

I made this change on the OMNIVIEW XE rom from CDY first.
These are the changes for the OMNIVIEW XE rom.

   ********** DAVID YOUNG are you listening. ***********

The changes....

EPROM ADDRS	OLD	NEW	
3FFC	29	20	power up reset vector
3FFD	EF	E9	power up reset vector
2920	44	AD	
2921	61	F2	
2922	76	02	
2923	69	C9	
2924	64	5C	
2925	20	D0	
2926	59	05	
2927	6F	A9	
2928	75	00	
2929	6E	8D	
292A	67	3D	
292B	20	03	
292C	CF	4C	
292D	CD	29	
292E	CE	EF	

     These bytes were used for Dave's title 'David Young OMNIVIEW XE (C)1985'. Sorry Dave, but this was the only safe place I could find!!!!

If you boot without basic his message will be messed up.

NOW THE XE......

     There are about 30 bytes of $00 in the rom at address $24A0. This area was reserved for jump vectors, but was never needed. The XE OS does a rom checksum during power up. So I changed that routine so it will always pass the check.

     This fix should also work on the XL series, but you may have to find a new location for the code.

The changes....

EPROM ADDRS	OLD	NEW	
3FFC	AA	A8	power up reset vector
3FFD	C2	E4	power up reset vector

```
3F90     38      18   defeat the rom check
24A8     00      AD
24A9     00      F2
24AA     00      02
24AB     00      C9
24AC     00      5C
24AD     00      D0
24AE     00      05
24AF     00      A9
24B0     00      00
24B1     00      8D
24B2     00      3D
24B3     00      03
24B4     00      4C
24B5     00      AA
24B6     00      C2
```

If you have both systems installed with a switch to select one of them at a time, you may want to make an additional change. Right now both systems use $5C for the first signature byte. You might change one of them to use a different signature byte. This would require finding all the places in the OS that it checks this byte and making the neccessary changes.

Once in a while, if your system is 'locked-up' it may take two attempts to get a cold start. It seems the first attempt gets the interrupt system working, then the second attempt does the coldstart.

NO MORE FLIPPING THE POWER SWITCH FOR ME.

Hope this works for you.

Ted Burger

I want to add an interface for a Hayes compt modem.
And I was told by someone there are a lot of serial interface availiable
, but I have no idea which will suit my requirement.
There are Atari 850, P:R CONNECTION (100 % 850 compt?), U-CALL and
R-VERTER.
Have you used any of the above?
Which one is better?
Thanks in advance.

*** REPLACE THIS LINE WITH YOUR MESSAGE ***

welcome to the club, i also recieved such a foul mouthed missive
from mrc; i was advised by people that i work with that know him
that he is a child and best ignored. I was also told that when he
left his last job to come out here, his old boss called his new one
to thank him, i don't know if that is true but after one email from
him i believe it. As my wife says consider the source and ignore him.

About using GEM from C:

Sorry, rb@ccivax, but there really are glue routines to get from C to
GEMDOS. The parameters to the routines have to be moved from the
stack to the "intin", "intout", "control", etc. arrays.

HELP!

I am trying to get a Mitsubishi 5.25 #M4853 80 track drive
to work with my ST.

I had problems with the select lead not selecting the drive
but I was able to buffer it and get the ST to find the drive
on power up. But know it will not format. There seems to
be a problem with stepping the head. The Mitsubishi drive
has a 3ms step rate and should work with the ST. Also
the drive does work on another (non ST) system.

Do any other lead(s) need to be buffered ?

I'd also like responses to this; I'm also interested in packages which
run on a Sun, and/or stuff available in source (C pref.), public domain,
etc. Anyone out there doing anything about programs which expedite the
DESIGN of musical notational symbols (NOT JUST the standard stuff)?

ATARI I/O PORT FUNCTIONS

A friend just bought a Radio Shack voice synthesizer and wants to drive it with his Atari computer. The synthesizer instructions call for a 13 pin connection to a host computer; his Atari has a male 13 pin peripheral port. The problem is that we do not know anything about the functional I/O of the Atari and hope there are some experts who can give us this vital information. Our questions are:

1. Are small computer 13 pin I/O ports all standard?
2. If so, what is the standard?
3. If not, what is Atari's standard?

Thanks for any and all help on this issue.

The RGB monitor is no problem since any medium resolution negative sync monitor can be used, however, the monochrome monitor requires a 31.5 KHz horizontal sweep rate and a vertical sweep rate that can be tweeked to 71 Hz. The 71 Hz Vertical sweep was chosen to reduce the

harringbone and barber polling that occurrs because of the internal frequencies present in the computer required to generate the color burst sync. Several monochrome monitors will fit this description if you are sure that the vertical freq. can be tweeked far enough.
  The monochrome monitor should have a high persistence phosphor so that flickering will be kept to a minimum. In monochrome mode, the video is output in interlaced mode and must scan two complete frames to complete one picture in the same amount of time that one frame is scanned in color mode. Thus the 400 line resolution in monochrome mode. There are rgb monitors that can scan at the 35 Khz rate and have a high persistence phosphor but their cost is around 800.00 plus dollars and that was evidently not considered a viable option. This would also require twice as much of aa graphics frame buffer also causing larger than needed overhead. The capability exists within the hardware to do this at a later date whenever the monitor technology get's to a more economical position. This would require different initialization of the graphics crt scan control registers as well as all the application software routines.

I am finding it difficult to open a window of my own using the wind_open

function in metacomco C. Has anybody got a piece of minimal code to do this?

Maybe the problem is to do with GEM global parameter arrays, but it might even be hardware.

I would appreciate information on 65/135XE documentation. All that I've seen so far is at a fairly high level. I'm particularly interested in something the equivalent of the Commodore Programmer's Reference Manual.

Thanks

A rough calculation (31500/71=444) indicates that the monochrome mode does NOT use interlace, i.e. all 400 lines are scanned in one frame (vertical scan) period. Thus a long persistance phosphor is not needed.

Does this power supply problem extend to the disk drive power packs on the earlier model 520's as well? I'd like to find this out before I run out in a panic and by a new supply.

ihuin!tfilm asks:

> 1. Are small computer 13 pin I/O ports all standard?

No way. Sorry.

> 2. If so, what is the standard?

N/A

  3. If not, what is Atari's standard?

(Assuming we are talking about 8bit Ataris, now) Loosely speaking, the
port is a serial TTL port which runs at 19.2 KBaud. It sends data in
frames with an address indicating which I/O device, and with checksums,
etc.

It would be lots easier to use the Joystick ports on your Atari. These
are 4-bit parallel I/O ports which use a standard peripheral interface
adaptor chip (sorry, I don't remember the number). The normal mode of
operation is to use them for input only for the joysticks, but it is
relatively easy to toggle a bit in the PIA and pump bits out.

Try such books as De Re Atari for details on all this.

There is an article in Analog magazine within the past couple of years
about constructing just such a thing as you propose using Shack parts.
You might want to look it up. I'm going to try it one of these days.

Burns

I'm thinking about buying a Qume/Sprint 12/25 daisywheel printer for my
520 ST.
I believe this is the one that 1stword supports, but I'm not sure.
Does anyone know?
Has anyone had any experience with this item?
Also, is $180 a good price?
Thanks.

<line eater>

I have a friend who is going to Australia for his sabbatical. He will
be taking a Macintosh with him. Since the Macintosh has a built-in
monitor, and the power requirements are '120v, 50-60Hz', I assume that
he will be able to use the machine down under, if he uses a transformer.
The Macintosh should work with the 50 cycles. Am I correct???

Part 2:

He also an Atari 800 which he will also be taking. The problem is much
trickier:

Using a TV:

-if he takes a standard colour TV, it will not work as a TV cuz the broadcast companies use a different format. PAL, I think, but different from Britain.
-it probably won't work as monitor for the computer using the RF output, cuz the TV is designed to work on 60Hz, not at 50Hz.
-if he buys an Australian TV it will most defineately not accept the RF signal from the Atari.
-I assume that if he takes a TV from here, that is capable of using batteries, ie converts the AC to DC before using it in any way, he should have no problems. The TV however will still be useless as a reciever of TV broadcasts.

Using a monitor:

-if he takes a monitor(eg. green screen) and drives it with the direct video signal, but has to plug it into 50Hz, will it work??
-if he buys a monitor in Australia, will it work with the signals that the Atari 800 puts out??
-is there an analog to the 'battery-driven' TV for monitors??

I am interested in any and all replies, comments, suggestions,

Thank you,

Warren Long

Does anyone out there know what is required to convert the dma port on the ST to a real SASI interface. I would like to use a fast 40mb st506 drive and sasi interface I already have on my ST. Apparently the developers drive has a little board with a half dozen 7400 series ics plus one pal and this then connects between the ST and an Adaptec sasi controller. How about someone with the developers drive divulging the contents of the "little board" and which model adaptec controller is used?

Is there a schematic with the developers drive? Could someone post it?

Although complete compatibility with the developer's drive would obviously be nice I can live without that as I don't see writing a custom device driver as a problem - so if anyone has ideas for an interface circuit that wouldn't be 100% compatible that would still be interesting.

BTW - I (and I'm sure a lot of other people) would like to know how people with the hard drives feel about them & their performance (and just what the price is).

Many thanks in advance for any help,

john chapman

My earlier postings on TeX for the Amiga has generated sufficient interest and enough common questions for me to post this information about TeX in general and TeX for the Amiga, ATARI, and Macintosh. First, some comments, and then a description of TeX.

I am currently porting TeX to the Amiga, ATARI, and Macintosh computers. The software will not be public domain; however, it will not be terribly expensive, either. For distribution details, send me mail (ROKICKI@SU-SUSHI) and I will add you to the mailing list I am building up. I am using the Manx C compiler for all three ports. The C source was generated from the public-domain TeX by a translator I wrote using lex, yacc, and C. The port will come in two pieces; the TeX package and a screen driver as the primary part, and various printer drivers in the other. Currently TeX works on the Amiga, and a device driver for the QMS KISS works on the Amiga. The port to the Atari is expected to proceed very quickly; the screen drivers will probably be the most difficult part.

It must be realized that the TeX system requires a lot of memory and disk space. TeX works on a 512K Amiga with two floppies, but LaTeX probably won't fit, and you might have to change the floppies occasionally. A nicely set up TeX requires a megabyte of memory and several megabytes of disk space.

Now for a description of TeX itself.

TeX is a computer typesetting system developed and placed in the public domain by Donald Knuth of Stanford. I believe that it currently stands unrivaled in terms of quality and power for typesetting documents, especially those with complicated mathematics. It is written in WEB, which is essentially a preprocessor for Pascal which introduces an incredible degree of system independence. (WEB also has many other attributes, see Knuth's Literate Programming article from an issue of Communications of the ACM a few years back.) The input to TeX is prepared with a standard text editor, and contains formatting commands much as troff. TeX is NOT WYSIWYG (what you see is what you get); the actual 'formatting' of the input has no relation to the output. Nonetheless, TeX is very simple to use; the equation for the two roots of the quadratic equation can be typeset simply as:

```
$$r_1,r_2 = { -b \pm \sqrt{b^2-4ac} \over 2a }$$
```

(braces group, $$ chooses display math mode). And the output is beautiful. Check out The TeXbook by Donald Knuth (Addison-Wesley, ISBN 0-201-13448-9, available at any college bookstore) if you don't believe me. The TeXbook is a user's guide for TeX, and provides an example of its power.

The output of TeX is a DVI (or device-independent) file; it contains a low-level page description. Device drivers are required to convert this file to the appropriate commands (or bit maps) for the particular device being driven. Some device drivers come on the distribution tape; others are available from various companies and Universities. If you have a particular device, send me mail and I will see if I can find a device driver; otherwise, I will mail you the particulars of a couple of companies which specialize in TeX device drivers.

TeX has been ported to an incredible number of computers; these include Vaxen under VMS and Unix, Suns, Amdahls, Apollos, CDC Cybers, DEC 10s and DEC 20s, DG MV8000 and MV1000, HP1000, 3000, and 9000; IBM MVS and VM, PERQ, Prime, Siemens, IBM PC's, the Macintosh, just about anything which runs Berkeley 4.2, and others. Thus, it is usually available for whatever machine you happen to use; like EMACS, this can help ease the transition when moving to a different computer and operating system.

TeX is effectively public domain; Don Knuth has granted permission for full distribution of TeX, provided that it is not modified in any way. The WEB system allows for implementators to make system dependent changes to TeX in such a way that the original source file does not change. The TeX software distribution is available from Maria Code for effectively a tape charge, and it includes literally megabytes of source. The tapes available are:

TeX generic distribution tapes (PASCAL compiler required):
   ASCII format, EBCDIC format
TeX specific distribution tapes:
   VAX/VMS (backup format), IBM VM/CMS format, IBM MVS format,
   DEC 20/TOPS-20 Dumper format
Font tapes:
   Font library at 200/240 dots per inch
   Font library at 300 dots per inch

The tapes are under $100 each. Call Maria Code at (408) 735-8006; her address is DP Services, 1371 Sydney Dr., Sunnyvale, CA 94087. Please do not ask her questions about TeX; I believe what they have there is effectively a tape duplicating operation.

A Unix port (for Berkeley 4.2/4.3bsd) is available from the University of Washington; I think the correct person to contact is Pierre MacKay, Dept. of Computer Science, University of Washington, FR-35, Seattle, WA 98195.

Address specific questions to me (ROKICKI@SU-SUSHI); I will answer them if I have time; I may just refer you to someone who knows. -tom

Summary: Horrible Aztec C BUG!!!

Just discovered a pretty gross bug in the Aztec C for the Macintosh.
If anyone uses the realloc function, expect random, devestating bugs.

The realloc function is supposed to change the amount of memory gotten from
a previous malloc. However, Aztec C (I looked at the sources, which are
included) implements this by first freeing the old block of memory, then
mallocing the new memory, and finally moving the old data to the new memory.
OF COURSE, ONCE A BLOCK IS FREED, ITS DATA CAN BECOME GARBAGE. In fact
on the Macintosh a subsequent malloc call after a free often causes the heap
to be compacted, expanded, etc.. each of which can trash the data.

The reason this code is written this way is a holdover from Unix, which
promises not to compact under certain circumstances.

The workaround for this is to call malloc yourself, then move the data, and
finally free the old block. The problem with this is that it requires twice
the memory of a realloc, because we have to have the old and new blocks of
memory at the same time. But at least it doesn't crash.

Their realloc routine may work as advertised on some systems; it depends on
the internals of the Macintosh. I found the problem when my Mac program
produced garbage at random intervals. Implementing my workaround fixed the
problem.

Note that Aztec C is an otherwise great package. However, I bought the
professional version for $500 and they didn't even include a lint. What
a ripoff.

I'm looking for a cheap PC clone; I've seen a lot advertised in the
$800-$1000 range, in varying speeds, qualities, and amounts-of-detail.
My primary concerns are reasonable compatibility, price, and speed, in
about that order, but I'd really like a >=6 Mhz model that can use an
8086, V20, or V30 instead of 8088. Are there any well-known lemons in
this price range I should avoid, or dealers I should avoid?

Alternatively, does anyone make an MS-DOS card for the Atari 520ST or
1040ST? Somehow a 68000 offers more promise than an 808*, and this
would be a good compromise.

Please mail any responses; I'll summarize and post.

              Thanks;

  In part answer to my own question about the screen size on the

monochrome moniter: yes atari meant for the viewing area to be
smaller than the physical screen size.

  However, there is a rather straight-forward way of fixing this
which is described the April '86 issue of ST Applications. If you
can't get a copy and want to know how to do it, I'll email
(or post, depending on whether there are more than 3 mono systems
around) a summary. BTW, this fix voids your warrenty (so what doesn't?).

  Another question: The display on my mono moniter becomes "jittery"
after the system has been on for about 10-15 minutes. The problem
disappears after another 10-15 minutes. ("Jittery" means that the
horizontal hold appears to be off, pixels alternate between their
proper location and one location to the right or left.) Any ideas
or previous experience with this problem? Is it in the moniter or the
ST? Should I consider this grounds to try and return the ST?
(And get another, of course!)

  I saw a 1040ST this weekend. As a previous poster said, it makes
a whining noise that I would find intolerable for more than a
few minutes. Any explanations or fixes? (Me, I'll have 1Meg after
the warrenty on my 520 expires!)

by TLM Systems, the folks who make one of the 680x0 boards that you can plug into an International BM PC and run OS-9/68000 on. The people who will sell it are some outfit I've not heard of, called MicroTRENDS. (Anyone out there heard of these folks?) TLM has been advertising pretty steadily in recent issues of *BYTE*...their address & phone:

TLM Systems

Help... I bought my 520ST to use to drive my MIDI keyboards, and don;t
find any documentation on how to access them. And since I understand assembler,
could some kind soul give me a quick hack of a routine that can read and write
to the MIDI ports. Also if there is any other documentation on them, please point
me to it. It would be nice to get some C code to go with the stubs... (wishful
thinking). If worse comes to worse, send me the address of the ports and their
status addresses. I'll hack something together from that.

i seemed to have misplaced the information about who
to contact for the atari developer's kit. could someone
out there post it or mail it to me?

could someone also briefly describe the advantages of
being a 'developer'?

thanks,
danny chen

The following program will give a rudimentary introduction to the ST's
MIDI capabilities. I pulled this from the net a couple of months ago.

I am looking to purchase a computer in the near future, and am deciding
between an Amiga and an Atari. I have heard good things about the ST,
but have some questions that hopefully some kind soul will answer (I
would ask an Atari dealer, except there doesn't seem to be one in Madison).

General Questions:

What is a 512ST? What is a 1000ST?
How much will I pay to get one, and what do I get for that money?
Details, like Processor, Disk specs, monitor, etc?

The major use I have for the thing is to drive the MIDI port. I want to
enter music and have it played to my Synth through the MIDI port. I would
like to be able to save music on disk, edit it, listen to it, tweak it, etc.
A convenient editing environment would be nice.

Is this possible? Who makes products like this for the ST and how much
do they cost? Does anyone out there have any of this stuff?

Thanks tremendously in advance.

derek

P.S. Also, if anyone knows of any Atari dealers in Wisconsin (or nearby states,
I guess) could you tell me about them?

Finally some MIDI software for my ST.

I finally bought a MIDI sequencer for my ST. I shopped around
and decided for 'Midirec-I'. Other contenders were 'Soundwave'
and something else whose name I do not remember.

The interface is simple and menu driven.

The basic features are:

```
     record up to 30,000 notes (less with key-velocity/pressure info)
     playback (with variable speed control)
        Save song to file
     Load song from file
     Built in metronome (really nifty, with beats/measure, tempo control and
             other nice features)
     +  others
```

MInimum requirements are a 520 ST with a disk drive, either monochrome
or color monitor (I have both ;-)).

The system is configured for future expansions such as patch librarians
and programmable sound effects.

I tested it on a Yamaha DX-7 and a Casio CZ-100 and it works without
any problems.

The program is really fast, written in forth, and they say you can
buy the sources to add your own features.

I discovered no bugs, and the price/performance was great.

After I decided to buy Midirec I went to the local music store
and they were all out, so I mailed 29.95 to the MIcroB (weird name)
people and got the program in 3-days (almost immediate gratification).

Microb's address is:

MicroB Software
1016 E. El Camino Real, Suite 392
Sunnyvale, CA. 94087

As usual

I am in no way related, even remotely to MIcroB software, and
all the usual stuff, just a happy customer getting the right
program for the right price.

jfb

P.s. Also, this is all only my opinion, and not that of my Employer (or
my mother).

Well, it's finally happened officially. OS-9/68000 for the Atari 520ST
and 1040 ST was announced and demonstrated at COMDEX in Atlanta last week.
Languages listed as available are Basic09, C, Pascal, Fortran, and COBOL.

According to messages on the CompuServe OS-9 SIG, support is already there
for all ST hardware, including MIDI and CD-ROM ports (the latter not being
too surprising in view of the joint Sony-Philips-Microware work on CD-

ROM). The fellow who saw the beast saw it running with an Atari 20Mbyte hard disk, with a terminal hung off the RS-232 port. Basic09/68000, alas, is still slower than one would like.

People there say that Jack and Sam Tramiel had it demonstrated to them and were VERY interested and asking questions. Plans are for a graphics interface (I would presume VDI, considering Microware's work with GSS) and a facility whereby one could run TOS as a process under OS-9.

TLM (the folks who did the port) also had their 68010 board for the International BM PC AT/XT running OS-9 there.

Messages on CIS from folks at MicroTRENDS, the company marketing OS-9 for the 520ST, say that OS-9 for the Amiga should follow shortly.

Does anyone know of a musical score editor, such as Roland's MPS, that will work on the 520ST. Any information on available packages,, either in public domain or not, (i.e., where to find it, cost, etc.) would be greatly appreciated.

Thanks in advance!

/* Written 11:18 am May 9, 1986 by chapman@sfucmpt.uucp in net.micro.atari */
Apparently os/9 for the ST was demonstated at comdex. Does anyone
know the price for the system? Do they supply any sort of windowing
system?
/* End of text from net.micro.atari */

Prices I've heard are as follows:

OS-9/68000	$250
+ Basic09	$299
C compiler	$295
Pascal compiler	$295

C, Pascal, and Basic09 jointly will go for some price I don't yet know,
but I am assured by a fellow at MicroTRENDS (a Schaumburg IL company that
is marketing OS-9/68K for the Atari and eventually for the Amiga) that
it will be <$500. These are "list prices," I presume; another message
on the CompuServe OS-9 SIG (which is where I get my data from) has already
popped up from a fellow who found a store that would sell it for a fairly
hefty discount.

Windowing? Not yet. Since Microware has gone for VDI with other OS-9
68K stuff, I'd presume that they would go that route here also. I
understand that one will shortly be able to run TOS as a process under
OS-9.

In <some magic # I don't get to see> George Frajkor writes:
> DOES anybody know if someone is developing a networking or shared-
>peripheral system for the STs?

Well, if you are running OS-9 on your ST, just get yourself NFM and
a driver for the flavor of network you want, and off you go.

                        James Jones

> is marketing OS-9/68K for the Atari and eventually for the Amiga) that
                        ^^^

This is the second time I have heard of someone developing software
for the Atari first, Amiga to come along later. Is this just a
coincidence or does Atari software have a bigger potential market?

I would be surprized if even a small number of people buy OS/9 for the Amiga.
It seems the main reason ST owners are interested in it is the multitasking
capability of OS/9. The Amiga already has this. To answer the question, I
think OS/9 was developed first for the ST because that is where the market
is for this product.

As an user, answering these two questions may ultimately benefit
you.

1. Would you like to have different colored diskette covers so that

you can more readily distinguish your disks at a glance?

2 a. Would you rather purchase brandless 5 1/4 inch diskettes priced at 50 cents each, or,

b. purchase brand name diskettes at $1.30 each?

Send your comments to riz@bucsb.bu.edu

Thank you for your co-operation with DISKOVERS, P.O BOX 684, Kenmore Square, Boston, MA 02215, U.S.A.

I have yet to find a decent editor to use on the ST. What I would really like to see is something like VEDIT, lots of power with simple, quick commands. Any recomendations?

Why not use EMACS?
You can use the same editor on your ST and on you mainframe.

Question:
Will the Atari ST run programs that were
originally designed to run in the IBM PC?

I know that is vague, so let me split my question
into two parts.

(a) Is there software for the Atari ST that will cause it
    to emulate a PC?

(b) Is there hardware (CPU, memory) that can be attached to
    an ST so programs run on the foreign CPU, but use the
    ST keyboard and screen.

(I know that ther are 68000 cards that one can put into a PC.
Maybe there a 8088 card to put into an ST.)

I've finally gotten both the RAM upgrade and TOS in ROM installed on my ST.

After discoving that the various public domain RAM disks don't work with TOS
in ROM and figuring out how to boot with old TOS, I tried OSS pascal. (is
there a PD ram disk which works with TOS in ROM?)

The results are staggering:

operation: All Floppy   ALL Ram disk Split

Compile and link

"hello, world"   1:20   0:05 (!) 0:23

Compiling 9k
GEM program   2:30   0:21 (!) didn't try yet.

The most intersting number for me in the Split number. In this setup I had
my source on floppy and the compiler and libraries on the RAM disk. The OSS
compiler and linker handle this very well, correctly loading the libraraies
from the disk the compiler is on while placing the source, object and final
program on the floppy.

I have a short analog clock program I posted to USENET's net.micro.atari a
few weeks back. It is written in OSS Pascal and I'd be happy to post it
here if enough folks are interested. If not I can mail source and uuencoded
binary to one or two folks.

I am a recent ST buyer, so bear with me if all this has been discussed
before. I have a vanilla 520ST except that I have TOS in EPROMs.

I picked up a hippo C compiler and started to try writing some of the
example programs. All was going well until I found that some of the
graphics interface routines appeared to be non-functional. No problem,
I figured I could write them in assembly and use my own names. Then
the real problems began. After trying everything I could think of
(I have been programming in C and assemblers for many years, so lets
not look for the obvious), my assembler subroutines still give me
bombs.

OK, maybe I was doing something wrong. I tried writing several
example programs completely in assembler. They work fine. Seems
to me this points to something in the linker/loader, as all the
bombers involved multiple modules with C and assembly mixed.

Anyway, anybody out there got some helpful hints for me? Even
if I find out that my $50 was wasted, that's OK, at least I can
stop worrying that I no longer understand anything about computers
the 68000 and C and assembler.

Thanks

There is an MS-DOS-type shell available that allows the normal MS-DOS commands: DIR, COPY, ... It seems to be a complete COMMAND interpreter. I'm not sure of the price, but is available from MichTron in Pontiac, Michigan.

I have used the Micro C-shell and have found some fairly serious limitations. For example, only one device (disk drive) could have a path pointing to a subdirectory; all the rest are forced back to the root directory. (This was a couple months ago, maybe it has been improved.) ...Ken Olson

Well, from the USENET side, things seem official, in spite of the small amount of bickering (:-). I've checked with A Prominent Net Personality, and he's including the new groups in the official list of newsgroups. So, we should start using the .atari8 and .atari16 groups, and remove the .atari (giving, of course, every interested site enough time to make sure they're up and running).

I don't get access to the US Atari mags (sniff sniff boo hoo), so any
continued information on if/when/whether OS/9 will be available is
always nice.

What I did get two days ago is an offer of the Lattice C-compiler.
Has anyone any experience on whether this is better than the Hippo one?
I have seen the Whetstone figures for the Atari, but do not know which
compiler they used.

The device in question was sold by SYNAPSE and called "RELAX."
It was around $69-$99 and quite fun....came with instructional
material and software....I have one and occassionally use (not often enough!!)

Since Broderbund bought Synapse, I don't know if it's still being made,
though...

Philon Software has a FORTRAN compiler scheduled for release around

April, 1986...They have already released the FAST-BASIC/M compiler
(retail $129), and it appears to be ok.

BUT....The FORTRAN is supposed to be $300 retail (a bit steep for the
ST market!,not that it might not be worth it)

If I hear anything further I'll post
ps...they also have a COBOL compiler scheduled as well!

These routines are taken from Comp-U-Serve. They allow you
to put a mono-system into 50 line mode and back again.

Question: How do they work ??? They index in the negative direction
from the pointers received in the line A call. My line A documentation
says nothing about anything in the negative direction.

Note: the fifty lines are quite nice... for those who are writing terminal
programs, editors, etc. this would be I nice option. I've modified some
of the public domain stuff to include this.

Note1: You can also have a 4x4 font but that hurts.

In answer to your question, "is an Atari touch tablet on of those
keypad things...": No. It is the same sort of thing as a Koala
Pad: a device which, when compatible software is used, allows
one to 'draw' with a finger/stylus on the pad, and the drawing
shows up on the screen (and can be saved to disk, etc.)

I just spoke with aa Atari retailer in Indianapolis that is offering some
pretty good prices on ST stuff. For Example:

1. A 520ST, Single Sided Drive, Color Monitor for $800.00
   Check or Cach Price (add 5% for Credit Card, add 5% for tax within IN)
   The price includes only the software that comes with the particular
   machine you buy. If you want all free software that Atari will eventually
   make available (NEOCHROME, STBASIC, LOGO, STWRITER) you should also
   include about four disks and $20 copy charge or $50 for a package of disks
   some of which will be used to copy the above onto (you keep all ten
   disks).

2. If you buy the above you may purchase VIP for an additional $125.00

3. If you buy the ST above you may purchase a second, double sided drive
   for $250.00

If interested give a call to Pat McGraw at 317-291-8882 or write

       Pat McGraw
       Microcomputers Inc.
       3350 N. High School Rd.
       Indianapolis, IN 46224

I have no connection with Microcomputers Inc. I have never even been there.
However, a friend of mine has been there so we know the place exists. I
cannot say anything about the service one might expect from this
organization. However, Pat was easy to talk to on the phone, seemed helpful
and WANTS to sell computers. What the heck.

I left out that the $800.00 ST has a guarantee. (apparently a seller
of STs has the option not to include a guarantee - in that case the
distributor knocks off about 4% or 6% (I can't remeber which))

If Atari doesn't aquire the Multi-Tasking GEM will DRI market it
themselves ?? Will it be in ROM ?? Will it have mechanisms for
inter-process communication? What kind of schedular is implemented ??
Actually it seems that the questions could go on forever... how about
a short description ???

Cmon guys - could one of you tell me which system routines to call to
be able to do very simple graphics (drawing lines, etc.)

My compiler (TDI Modula-2) supports all the GEM, AES, VDI, etc
but I don't know what routines to call.

My compiler came with a large graphics demo program, but I can't figure
out what I need from that, and what is unnecessary.

If someone could send me a simple example program that gets the computer
into graphics mode and draws a couple of lines, I would really appreciate
it.

Please help me out!

Thanks in advance,

I have found that Mike's RAMDISK works conditionally with 1MEG and TOS in
ROM. Mike's RAMDISK can be set to any size above 100K. It has the following
drawbacks:

1. It seems that if one originates execution of a program from a
   floppy drive some avaiable memory is lost (until the next boot).
   However, this does not seem to happen (except perhaps initially)
   if one originates execution from the RAMDISK.

2. My version of Mike's RAMDISK does not allow resizing of the RAMDISK.
   But this is a relatively minor drawback.

I have found this RAMDISK very useful - especially for compiling in C
using the developer stuff. I simply open 'er up to 700K, dump all
the .h, .o, library files, compiler and linker and source into the
RAMDISK and let 'er rip from device D. I have made up to 15 straight
compiles without a problem this way. Also, the time for compile has
been as low as 40 seconds (must be a world's record for the DRI C)
on small files (producing 15K executables). At the moment I can easily

live with this RAMDISK and I recommend it to anyone needing a stopgap
until a real RAMDISK (occupies upper memory, allows resolution change,
can be resized, size at boot can be preset (even to 0), no memory loss
through executions etc.) can be developed. Frankly, at this point I am
so fed up with PD RAMDISKs that I will go out and buy one once I know
there exists one that meets my specifications. If anyone can help out here
please do!

In the previous response I said i was fed up with PD RAMDISKs.
This was a rather unfortunate statement to make - it shows a lack of
regard for those people who are kind enough to produce useful software
and place it in the Public Domain. I very much appreciate most of the
PD stuff I have gotten (and Mike's RAMDISK is one of my most important
pieces right now) and I am sorry for being rude. When I learn enough
about the ST I suppose I will either fix Mike's RAMDISK or originate
another (unless a good RAMDISK shows up first).

<Mmmm, tasty>

I've just started using my 520ST for things other than terminal emulation,
and I have a few questions for anyone who may be able to help me. I have
the developers kit, but not much else.

1) Does anyone know how to convince the Control Panel not to nuke
   the time? I wrote a program to put in my "auto" directory to
   set the time. It works fine normally, but when run from "auto"
   it apparently sets the time, only to have it overwritten by
   the control panel accessory at startup. Any suggestions??

2) Can a desk accessory be written such that it runs to completion,
   and simply terminates (As opposed to sitting around in an infinite
   loop of sleep calls)? Specifically, I have in mind writing an
   accessory to run through an 'auto2' directory, and run stuff
   AFTER all the desktop information is set up.

3) Has anyone got a copy of a public domain RAMDISK that works?
   The person who gave me mine mentioned that there was a bug, but
   I never saw any fixes come by.

4) Has anyone gotten RTS/CTS handshaking to work well? I have my ST
   hooked directly to a UN*X box at 9600 baud, and RTS/CTS doesn't
   work at all. I'm not positive it's the ST's fault, so I'm just
   looking for verification.

There are a number of bugs in the InOut module for TDI's Modula-2 compiler. I saw recently on info-atari that someone was having touble reading integers from a disk file. Here's why:

Procedure Read does not convert CR-LF pairs to a single EOL character, but returns both characters individually.

Procedure ReadString does not stop reading when it finds a trailing space, but goes up to the next control character. Since ReadCard and ReadInt use ReadString, if you try to read several integers or cardinals from a single line, you will get a runtime error (#9) because a string with embedded blanks is not valid for conversion to those types.

Due to the bug in Read described above, ReadString will find a null string at the end of every line, sandwiched between the CR and LF.

Procedure Read sets the Done flag to FALSE one character too soon. Upon returning from Read after reading the last character in a file, I find that Done = FALSE. That should be so only after a Read call made AFTER the last character has been input. Done is a signal that Read HAS failed, not that it WILL fail.

Variable termCH is always set to 0C after a call to ReadString, ReadCard, or ReadInt. While it is true that 0C is used internally by TDI Modula-2 to terminate strings, termCH is supposed to be the character on the EXTERNAL medium that caused the procedure to stop reading, e.g., a space, a control character, or EOL.

Procedure Write, when called with EOL as the argument, just writes the one character. Therefore, Write(EOL) is not equivalent to WriteLn, which writes CR-LF.

The following, while not exactly bugs, I consider to be annoying mis-features:

Although the OpenInput and OpenOutput procedures take a string argument called defext, it is ignored. I think that the argument is allowed only for compatibility with other implementations of Modula-2, but the manual doesn't say that.

The screen is not placed in some standard state when a Modula-2

> program starts. Therefore, where the first output appears depends upon where a previous program left off, which might be anywhere. I would like to have the screen cleared and the cursor homed automatically on start-up. There seems to be no simple way to do this myself without using VDI.
>
> A null string "" is allowed as an argument to a procedure that has a VAR ARRAY OF CHAR formal parameter, as is a string with multiple characters. A one-character string constant is not, being considered as type CHAR. Apparently this is due to the fact that open array parameters must be declared VAR, that type CHAR is not compatible with ARRAY OF CHAR but only assignment compatible, and that the types of arguments given for VAR parameters must be compatible with the type of the formal. Whew! Isn't this taking strict typing too far?

I called the TDI offices in Dallas about the bugs, and will be sending them documentation sometime this week. I was told that it will probably be a couple of months before fixes are sent out, partly because all development work is done in England, partly because a new release of Modula-2 is planned for then anyway.

To tide me over until then, I am going to write a new implementation module for for InOut. I will gladly share it with anyone who wants it, but I would like to make it as "standard" as possible. There are a few details of the implementation that Wirth does not make clear in "Programming in Modula-2" (second edition).

> Under what circumstances should ReadString return a null string? From Wirth's description, it seems that it returns a null string at the end of every line that has more than one trailing blank. That would be a nuisance if you're trying to read a text file word by word.
>
> Shouldn't leading tabs be skipped by ReadString as well as leading blanks?
>
> What provision is to be made for signalling end-of-file for terminal input? A program that tests the Done flag should be able to read from a terminal as well as from a disk file.
>
> Assuming that ReadCard and ReadInt use ReadString, what should they do if they read a null string: return zero, cause a run-time error, or keep reading (with a prompt for terminal input)?

Let's have some discussion about this. After all, programs using InOut are supposed to be portable.

Subj: --- Compiler from Action! ---

Have heard nothing further, sorry. Next time I get to the OSS BBS
I will leave a note there, but there is no guarantees as to when
I shall call them next....

Also, have you a routine that will translate Action! format arguments
onto the stack (ala Basic USR call) so that all the nifty routines
written to use with basic could be directly ported to Action! with
just the addition of the USR interface?

```
PROC Grebnitz=*()
[ numbers numbers numbers ]

...

USR(Grebnitz, arg1, arg2, arg3);
```

If you have no idea, perhaps you could forward this query to the
INFO-ATARI8 list in general. If I don't hear from you in a couple
of days, I might get around to doing it myself....

>....!ucbvax!hplabs!amdahl!drivax!holloway

From the horses mouth yet!!

Since he's to modest to point it out, GEMDOS has many other nice
characteristics that CP/M didn't, like direct interface to high level
languages like C (especially C). This eliminates the need for the
time consuming "glue", of interface routines that stuff things from
the stack into registers, and back. The calling technique is not
much different from UNIX calling proceedure. Push arguments, trap,
pop or "drop" arguments, you're done.

To answer the original question (interfaces to OS calls), you may
find "ST Internals" and "Gem Programmers Guide" from ABACUS to be
quite useful. These books are about $20 each. The developers kit
is a good investment if you want to do some heavy programming.

Important note if you use the DRI C compiler, it uses 16 bit "Ints".
Assignment of ints to pointers, even with casting, is non-portable.
Using 16 bit Ints make things run lots faster too.

There are several good "shells", ranging from the command.prg, to
one that has most of the features of csh.

Since DRI is on the net, maybe they can tell us more about TOS/GEMDOS
re-entrancy and multitasking capabilities. Assuming we know about
the 6 desk accessories plus various drivers, is it possible to add
a real-time clock interupt handler that can do the AES calls automatically?
(AES "Application Environment Services" is like the "system scheduler"
in UNIX, but currently has to be "called" periodically to give other
processes a chance to execute.)

Any plans for multiple forground tasks?

Any plans for multiple background tasks?

Pre-emptive multitasking?

Assuming there were some tradoffs to make the forground application
run faster, is it possible to alter these tradoffs? If it is trivial,
could you give us some hints?

Lines: 53
Keywords: density, percom
Xref: watmath net.micro.atari:2904 net.micro.atari8:8

[]
In response to numerous requests, I am posting some info on drive density
switching:

To change density, you must call SIO, after setting up the IOCB as follows:

Device=$31   (D)
Unit= Drive #
Command= $4E (N) to READ CONFIG
       = $4F (O) to WRITE CONFIG

Byte Count = 12
Aux Bytes= (not normally used, but some DOS's use as part of formatting)

Also a "P" command is supported by some drives (like INDUS) to reconfigure
on demand prior to formatting.

The bytes transferred are:

byte 0: Tracks per side (40 std)
     1: Drive step rate (west. dig. std....0 fast 3 slow)
     2: zero (hi-byte of sectors/trk)
     3: sectors per track (18 for std...26 for 1050 mode)
     4: number of sides (0=single 1=double)
     5: disk type:
         bit 2: (0=single den, 1=double den)
         bit 1: (0=5-1/4"   1=8 ")
     6: hi-byte bytes/sector (0 for 810 compat)
     7: lo-byte bytes/sector (128 for 810   256 for double den std)
     8: translation byte:
         bit 7: (1=40 trk on 80 trk drive)
         bit 6: always 1 ...indicates drive present
         bit 1: 1= make boot sectors (1-3) full size
         bit 0: 1=sectors numbered 0-17 not 1-18
     9-11: undefined

These bytes are transferred TO the progran on a read config, modifications
may be made, and a WRITE CONFIG will change the desired options.

The comment about it not working on an 810 is specious....Obviously
these commands will only work on configurable drives...like PERCOM, INDUS,
ATR8000 controller, etc.

On more note; thos using MYDOS are prompted for these options when using
menu selection P from DOS...It internally generates the CONFIG command
and executes it. I have placed a BASIC program to configure drives on
some ATARI bulletin boards, but I'd have to look for a copy now...
It's been several years since I wrote it!

Some of you ST owners may have gotten a copy of the desk accessory called "ST Font Loader", as described in the January 1986 issue of Antic. It does a really nice job of redefining the standard font used by the ST for all its text. There are about a dozen font files available.

Unfortunately, this program does not work with TOS in ROM, as one of the authors, Patrick Bass, hints might happen in one of the early paragraphs of the article. Just to check if this problem had been corrected, I just called Antic and talked to Patrick. He said the main thrust of the article was tutorial in nature, rather than describing a solid application. The problem, he said, was that the program directly overwrote the character set used by the ST. This character set is now is ROM. A workaround would be to store a character set in RAM, and change the character set pointer so that it points at the RAM version. However, he has no plans to do this in the forseeable future. (Too bad, I wanted an updated copy for our club's library.)

Sooo, looks like a good project for someone out there!

Since I've been making a lot of noise on this subject, I thought I would
follow up with a different view.

For those in 68K who were just included, the question has been raised
as to the possibility of a "Standard OS" for the 68K machines such
as Amiga, Atari, and MacIntosh. Unix and OS-9 have been proposed
and discussed at length in both net.micro.amiga and net.micro.atari.
Consensus thus far has been that Unix has expensive requirements
(MMU, Memory, and Hard disks) which would cause prohibitive pricing.
OS-9 is a "hot contender", but seems not to be well supported. Since
the focus of this debate involves current and future small, graphics
oriented 68K machines, followups should be made to net.micro.68k.
Any and all systems should be discussed.

Ideal candidates should:
Be multi-tasking (True pre-emptive).
Include "Virtual Device Interface" for graphics devices.
Support a "generic graphics file" storage/transfer mechanism for allowing
     use between applications and machines.
Be portable to a number of machines (particularly Mac, Amiga, and ST)
  preferably using the "BIOS/XBIOS" or whatever low level drivers are
  currently in the machines ROM. If it can run on a SUN or something
  big and powerful, so much the better.

Other factors:
Ease of use to both application programmers and end-users.
Hardware requirements (no MMU, small memory, floppy disks).
Expandability (adding drivers without re-linking, sharability of driver code).
Modularity (Runnable with or without graphics "Desk Top"...)
Language support.
Price.

To start, let's make it a "brainstorming session".

For a given OS, tell what is good about it, where the "missing pieces"
might be found, special features, third party support,etc..

Let's try to avoid shooting things down initially.

   Re: the recent note pointing out the deficiencies of the TDI InOut
   module:

   Actually, I think the problem lies in the TextIO module. I've had
similar problems to those described while using TextIO. Here's what I'm
trying to read: a file of CARDINALs (one to a line):

```
1
2
3
4
etc...
```

I was trying to use:

```
 LOOP
    TextIO.REadCard (stream, c);
    TextIO.REadLn (stream);
 END;
```

but unfortunately, TextIO doesn't work as you'd expect (so what's new?)

Here's what I've actually had to do in order to get this to work: I've
changed the file format to put a blank line in between each CARDINAL. Thus:

```
1
```

```
2

3

4
etc.

and i've had to change my code to:

 LOOP
    TextIO.REadCard (stream, c);
    TextIO.REadLn (stream);
    TextIO.REad (stream, DUMMYCHAR);
 END;

talk about a kludge...

-------------------------------------------------------------

Also, I've noticed that the TDI compiler doesn't check function return
value types, thus:

   PROCEDURE p () : Pointer1Type;
   VAR
      p2 : Pointer2Type;

   BEGIN
      RETURN p2;
   END p;

is *NOT* flagged as an error.

-------------------------------------------------------------

Also, I've had trouble using Strings.  Say you have a proc:

   PROCEDURE p (VAR str : ARRAY OF CHAR);

You can't call:

   p ('this is a string constant');

But you can do:

CONST str = 'this is also a string constant';

  p (str);

-------------------------------------------------------------

Also, when I try to use a Set constant with about 30 elements (they *say*
that they can handle them...) then do a:
```

```
   IF MyVar IN BigConstantSet THEN
    ...

I get MUSHROOMS from the COMPILER !!!!
```

=-=-=-

pattern index, and fill color.

Some of the graphics calls are:

v_pline... draw a polyline
v_gtext... draw text
v_fillarea... draw a filled polygon
v_contourfill... perform a flood fill
vr_recfl... draw a filled rectangle
v_arc... draw an arc
v_pieslice... draw a pie slice
v_circle... draw a circle
vs_color... set one of the palette colors
set_color... set polyline color
set_type... set polyline type (solid, dashed, etc.)
set_effect... set text special effects (bold, italic, etc.)
set_interior... set fill interior style (hollow, solid, dots, etc.)

There are _lots_ more -- you really need the book to get all the parameters.

Summary:

I would like to add that MYDOS is not the only DOS that provides

a command to configure (incl. switch density) such disk drives.
DOS XL (from OSS) provides a CONFIG command that lets you specify
single or double density and single or double sided for each
drive. (My Percom drives will change density, but are only
single sided, so I can't vouch for the usefulness of the
single/double-sided switching.)

Since BASIC and Logo comes packed in _every_ ST we have sold for the last 2
months, and we are also packing 1st Word and Neochrome currently, there is
something fishy about the copy charges. Legally, a dealer _cannot_ copy
BASIC, Logo, or 1st Word. We have granted permission to copy Neochrome and
ST Writer for free. $5 apiece is a tad steep for copying 2 disks.

Well, back to gossip...

You should all be satisfied with Byte magazine now. It has chosen the 1040ST
to become the computer that will head the March issue; the second time; whereas
the Amiga has only shown up once in the Byte headlines...

And away we go...

The American National Standrds Institute document ANSI X3.4-1977
titled "Code for Information Interchange" is the reference source
for ASCII.

There are items on page 10 (Line Feed and Carriage Return) and on
page 17 (Interoperation of "LF" and "NL" ASCII Equipment).

The page 10 entries clearly state that a single character "New Line"
function should use the "Line Feed" character for this function, i.e.
the existence of such a function is context dependent but if defined
it is to use the hex 0A code. This is the convention that Unix uses
for internal storage of text.

In any case the "Carriage Return" has no standing as a "New Line"
character. This is certainly appropriate since we need to use it
on many printers for overstrike functions, e.g. underlining.

Some brain damaged systems designed by people ignorant of the standard
actually store both the "Carriage Return" and "Line Feed" within data
files as a line break code, thereby wasting an average of 2 - 5 % of
the file storage space and complicating the programs which deal with
these files.

The item on page 17 defines the combinations to be used in sending

to mechanical devices so that the action produced will be consistent
whether the device follows the "New Line" interpretation of code hex 0A
or not.

If conversions of the single character representation to a two (or more)
character representation are desired this is appropriately done at the
device driver level (and is universally available in Unix terminal port
drivers).

The writer who complained of getting standard representation in files
transferred from Unix to another operating system has a deficient
file transfer program for the environment (between two operating
systems) in which it was used.

Dear Folks on net.micro.{amiga,atari}:

There's the guy (an Atari-owner, and a rather proud one) who tells
me something about since the original Amiga development work was
done at Atari, that with every Amiga sold, Commodore pays a
commission of some sort to Atari. Is there any truth to this?
Responses from people at C-Amiga and/or Atari (Mr. Dyer?) would
be greatly appreciated.

Much thanks,

--

Bias: I *LIKE* inter alia RSX-11. I realise I may be the last person in
North America to do so.

Idea: Could O/S hackers please make the file system detachable from the
rest of the O/S? This requires treating file systems like they
existed at the other end of a network, and doing remote procedure
calls like "create a directory entry for file X and give it name Y".

An immediate benefit of this is that when you plug a FOO-format
diskette (or binary file) into a BAR-machine all your ordinary
utilities keep working but they use a different name for the
diskette drive in order to use a different file-system server.

More: To do this, you distinguish between a "device-driver" which hides
those details of hardware to horrible for ordinary mortals to
behold and a "file-system" which assigns meanings to the bit
ingested and egested by the device-driver. Not only is this
wonderfully useful for disk file systems (eg using Un*x utilities
to help manipulate CP/M disks) but the same idea fits very well
with terminals. You use a "crt server" to do such things as
"scroll window" and this is converted into messages for a "device
driver" which tickles the screen to acheive the task.

EG: DEC (perhaps to protect some marketroid's career by inventing one
more artificially distinct product) sells different flavors of

files-11 on different (PDP-11 based) boxes. I recently moved a lot of my file utilities (written in C) from an RSX box (where I had to use numbered, non-heirachical directories) to another PDP-11 in a terminal, which had named, heirachical directories. All my programs worked 1st time on these new directories & file names. By the way, I *ONLY TRANSFERED THE BINARIES*. No compilation was needed to let the programs work with a 'new' file system. I also moved some utilities (for which I had no sources) and they worked 1st time too.

Refer: RSX-11 has "Ancillary Control Process"s (ACPs) for file systems. They mix and match with "Device Drivers" which bend the bits. (I know about "class drivers" Virginia, but this is complex enough without recursion, reliability etc issues!) Likewise they have "ACD"s for terminals. Since Vaxen are ubiquitous (and often more 'respectable' you might want to read about ACPs (same concept) on vaxen.

I realise that the usual "Un*x is good enough, don't force users to learn more concepts that they need" argument applies. I suggest that the discipline of embedding remote proceedure calls into your operating system (just so it can survive the '80s) will both help you to better organise the un*x concepts and may allow you to flush certain concepts that become redundant as other concepts are generalised for a network environment.

If you don't think the "un*x concepts are good enough" argument applies, I could be persuaded to post a similar rave about why I think embedded delimiters in files (eg '\n' in un*x) are a lose. My counter-examples would be based on files-11 (because so many people have access to it) but I got the idea from CDC 60-bit machines and refined it making pdp-11s emulate IBM mainframes (faster that real time!!).

I trust (of course) all you O/S hackers will distribute source code to the net. This will give users enough confidence that *someone* near them will maintain the O/S that they will be happier to commit to the O/S.

Does anybody know of a good RAM CACHE program or algorythm?
Asynch read-ahead, and write would be nice, along with demand
based purging.

Such things are available for other machines, and appearantly
save you some of the grief of powering down the ram disk before
you've put it back on floppy. I've also heard they're real nice
with hard drives. I know very little about them exept that they
make a machine look like it's running faster.

Is this an OS/Driver hack?

I bought a 520ST on January 4, 1986 and it promptly self-destructed
within a few weeks (Power supply went bad, putting out excess voltage,
thus destroying keyboard). The machine was returned to the dealer
on January 16th who promptly sent it to the distributor who in
turn supposedly (?) sent it to the service center.

Well, it is now March 1, 1986 and I have not seen my 520 since January
16th. Repeated calls to the distributor are always answered with
"You'll have it next week".

I do not want to name the parties involved at this time because there

may be a good excuse for the delay (even though I don't know what
that excuse could possibly be). What I do want to do is let the
net know that service on an ATARI 520 can be a headache!!

Has anyone else had such an experience and can you recommend how I
can get my 520 back?

All of what I said in this note is what I was told by the dealer.
Buyer Beware.
Thanks, Neil, for getting things straight

Incidentally, the dealer really is under the impression that there are
two prices - one with guarantee and one without. Also, it seems I have
heard this someplace else.

The school I go to is seriously thinking of computerizing the Art Department and the Industrial Arts. I REALLY NEED reviews of each of the following computers (reviews not only about the machine but software too): Amiga, Atari 520, Mac, and the Tandy 2000.

I need reviews in the following areas: cost, hardware (what comes with the base unit and what is available not just from one particular company)*, software (what comes with the machine and what is available)*, support (technical & demonstration for hardware AND software), bugs, and problems.

*-Please limit the topic to hardware and software pertaining to art and industrial art (mostly drafting).

No publications of replies will be made other than maybe the net if there is enough replies for a good-posting.

I will accept any reviews dealing with any of the computers I have listed. ALL will be valuable to my report.

Thank you,
Gregg Thompson

P.S. PLEASE do NOT post replies, instead mail them to me.

Oh, you mean the things which, I believe, DEC got rid of in recent VMS releases? XQP's (eXtended QIO Processors) are their replacement, and may also be pluggable in the same way.

> I realise that the usual "Un*x is good enough, don't force users to learn

At the risk of turning this into a plug, I might point out that Sun 1) put a switch mechanism for file systems into our UNIX, into which are plugged a 4.2BSD UNIX file system, an MS-DOS file system, and a network file system, and 2) the network file system in question is based on remote procedure calls, so any lack of such a mechanism in UNIX is a matter of implementation, not concept.

> If you don't think the "un*x concepts are good enough" argument applies,

I don't think that's what you meant. I sincerely doubt you can make a
PDP-11 of any flavor execute 3[67]0 code faster than a 3090 can. *Maybe*
faster than a 360/30 (easily faster than a 360/20, but whether that deserves
to be called a "mainframe" is questionable).

Nevertheless, I'd be curious to see the rave in question - posted to "net.os"
(which has seen no postings recently), *not* to net.micro.68k, since it has
nothing to do with 68000s.

I am interested in doing some software developement on my ST. Several friends
have the Atari developers package and/or Megamax C, and my general impressions
from listening to them are that:
    1)DR C is unbearably slow in the link stage, and the Megamax C is faster
      in compile/link than the DR C links out of a 1040K ST ramdisk.

2)The developers pack documentation is big, but rather difficult to sift through.

I am interested in creating my own SIMPLE multitasking operating system and also a compiler as a school project, so I do need rather complete and documented BIOS listings, addresses, GEM info, etc. What I would like is a review of Megamax C from anyone doing developement work with it. Please describe:

- compile/link times
- quality of code produced
- documentation and support
- bugs and quirks (does code longer than 32K have to be broken up and linked like Mac Megamax? Is this a problem? etc...)
- features (ease of gem support, floating point accuracies, etc)

While I lean towards C, I am not adverse to other languages. I would also like to hear from those doing developement with other products. Any comments on other C's, Modula's, Pascal's, Forth's, or other languages is appreciated.

Also if you have any information about the knowledge that may be gleaned from Abacus books 'ST Internals' and their GEM reference manual versus Atari doc's you might pass this along as well.

thanks! -Sam

P.S. I confess to being a complete novice at the net. Please direct your responses to me here, wherever here is on the net (Aye, there's the rub) or via the US Mail to

I really don't know why i should do this except that there is no justice

in this mortal world; those who are right not only have to pay their own way, but that of those who are wrong, too (e.g. it costs more to keep Charlie Manson in free room and board than i make each year). It would seem to me that anyone who knows enough to get on the list at all, should be able to get the correct information the same way that i did. Nevertheless, here it is, quoted from the info-atari mail archives...

Mail-From: G.ABRAMS created at 28-Jan-86 19:09:36
Date: Tue 28 Jan 86 19:09:36-PST
Subject: Announcing INFO-ATARI8 and INFO-ATARI16

Direct contact with INFO-ATARI@SU-SCORE will change as follows: Two new lists have been created INFO-ATARI8 and INFO-ATARI16. They are both copies of the original INFO-ATARI. Please send a message to INFO-ATARI-REQUEST@SU-SCORE for additions and removals from either list. Presently, INFO-ATARI will point to INFO-ATARI8; eventually it will be removed.

There is a mirror between ARPANET/DDN mail as described above and the Usenet news group net.micro.atari. We are working on getting it replaced by net.micro.atari8 and net.micro.atari16.

If there are similar mirrors to other bulletin boards and information systems, their administrators should send mail at once so they can continue to receive messages.

++FLAME ON++
The question is: have you even *TRIED* using net.micro.atari16?
++FLAME OFF++

>no general interest material - belong at info-atari8.

   It's been my observation that a lot of the flaming and misunderstanding regarding ARPA connections has to do with the connection itself, and is not attributable to the "cretins" on either side of the electronic curtain. Being on USENET, I personally don't (and more importantly, shouldn't have to) take into consideration the fact that somebody may take my posting and route it into another network. After all, it's kinda rude to take a perfectly acceptable USENET article from net.micro.atari onto the ARPANET, and then complain about it. Likewise for us USENETters complaining about all the "delete me" and "add me" messages. Perhaps some education on both sides may help. Being admittedly ignorant about such matters, I wouldn't mind some educating myself.

A co-worker is need of replacement parts for his 800XL.Specifically he
needs a new cpu chip(CO 14806-03) and an ANTIC chip (CO 12297).
Note: the cpu in an 800XL is not a standard 6502.

Mike

Help!!

Can anyone tell me where I can ftp a copy of Atari Kermit that will
allow me to communicate file transfers with a multics host.

Please send information directly to me at Knott -at Dockmaster.

Thanks in advance.

The only clue about how to do graphics with TDI Modula-2 is the source code
of the demo program included in the manual.

The demo program seems to use many more routines than I need to use. I simply
want to be able to set and clear pixels on the screen (i.e. plot points with
integer coordinates in a 2-dimensional cartesian plane).

Could someone tell me what routines I will need to use, and perhaps even
how to use them? If someone could send me a program that just plots some
pixels to the screen given their x-y coordinates, that would be sufficient.

I am working on the program for plotting the Mandelbrot set mentioned in
Scientific American, August 1985. When I finish it I will send source
and object code to net.sources.

Thanks in advance,

Eric Terrell

Summary: All things are possible...

Two things here - 1. I have, after some hacking, managed to turn SAM into an AUTORUN.SYS file. For my next trick, I'm going to try making it work in ACTION! (Why couldn't they pass the address of the string to the USR routine?) This is obviously because ACTION! beats the solids out of BASIC (& everything else on 400/800/XL/XE) but - you should be able to copy SAM. Lemme see. Find MEMLO. Find where DOS finishes. Go to DOS and save memory between these points as AUTORUN.SYS. Add a small .OBJ program to keep MEMLO where SAM thinks it should be (just append it on) and it should work. If anyone wants details I'll be happy to mail.

The source for SpeedScript 3.0 is available in a COMPUTE! Books publication
called, appropriately enough, "SpeedScript 3.0". It is available at many
computer book departments. It also contains a reasonable user manual for the
program.

Summary:

[]
David mentions reading sector 1 to switch densities, but I don't believe
that is what was asked, or will in fact help.

In fact, to insure compatible booting, the first three sectors are
always 128 bytes, even if 18 X 256 DD formatting is used on the
remainder of the disk.

Most switchable drives use additional commands (M, N, O) to switch
density according to a table passed in the call. These are documented
by manufacturers using the system developed by PERCOM, and copied
by AMDEK, ASTRA, TRAK, INDUS, etc. (even ATARI)....

If you need the table layout, I can probably dig it up....

Curiously enough, that's EXACTLY what they were talking about. The
note quoted was in response to a note complaining about "Please drop me
from this mailing list" notes appearing here. It's not nice to
flame people when you're only guessing what they're talking about,
even when you have the sense to acknowledge in advance that you
might be wrong...

I just asked Applied Computer Associates (in Gaithersburg, MD, a Wash. DC suburb) about the 1040ST and they also said "middle of next month".

Incidentally, they are a very serious Atari dealer, with lots of software and accessories for both the ST machines and the XLs. They can be reached at:

PHONE: (800)-4-ATARIS (428-2747)
(301) 948-0256

MAIL: Applied Computer Associates
16220 Frederick Road
Gaithersburg, MD 20877

In particular, they have some of the harder-to-find Atari books in stock.

Does anyone know how to redirect standard output to the printer in the Digital Research C compiler? The manual included with the ST developer kit suggests that directing output to /dev/lp or to LST should work, but in each case these produce a file of the same name.

Does anyone know how to redirect standard output to the printer from within a C program?

The getchar routine (also gets) do not respond to the RETURN key, they just wait for you to type another key (They treat CONTROL-RETURN as a return). Does anyone know of a clean fix for this problem? At present I am using Cconin and anding the result with 0X7F, but it takes a good bit of

reprogramming to get the effect of gets including the correct action on
CONTROL-h, etc.

Following the arrival from Atari of a large box, I can report that a megabyte expanded, twin floppy, one hard drive, OS rom Atari 520ST works fine. The recent suggestion that the OS roms cannot use the megabyte is not true in my case, and I have an early model, serial number 1782.

The real reason for posting is to ask if anyone is developing network interfaces for Ataris, especially Cambridge Ring, or Ethernet. I am told someone in the US is supposed to be developing the latter. Any information greatly appreciated.

Nigel Roles

This message is coming to you via a 1 Meg upgraded Atari 520ST with TOS in ROM but with no (i.e. zero) resistors in the RAS and CAS lines of either memory bank. It appears the resistor myth is exploded (but not the ST).

Of course there are two reasons why all of you 1 Meggers should not throw your resistors away yet:

1. My machine might explode tomorrow or next month or in July.

2. I may have lucked out and used DRAMs of somewhat different character than those used by the one other person reporting memory failure.

In any case we now have 1 failure and 1 successful ROMing without resistors. Anyone else care to try?

With regard to 1. if something happens to the memory in the near future (say a couple of months) I will broadcast that info immediately. With regard to 2. I used bottom of the line Hitachis.

   Does anyone know of a mail-order place that carries the Atari Touch Tablet? I believe it's part number CX77. I've called a number of places that advertise in ANTIC and ANALOG magazines and have been unable to find one. Any info would be appreciated.

We're here! Landon Dyer has not got me wired up to our VAX yet, but I have managed to find my way into usenet anyway. Hope I can find a good book on Unix in a hurry!

The next shipment of 520ST computers will have the following video signals:
70 Hz High-resolution monochrome (works on mono monitor ONLY)
60 Hz RGB Analog
      Composite Video
Modulated Rf signal
    The last 2 on the list are new. All _except_ monochrome will work on color modes, low & medium res.

The new ST systems are due any day now. Hope this message gets out to you all am still learning this...

I would have to vote yes, if I had a vote. I have no interest in the 520ST: my personal opinion is that it's a pretty good IBM lookalike with a 68000 in it: not a true next-micro-generation machine. On the other hand I do use an 800 and find it quite usable for mucking around on.

Speaking of which...

Is ACTION! the only decent compiler available for the 800? I'd kind of like to keep some sort of compatibility with my IBM and UNIX 'C' programs.

I read an article in the Baltimore Sum on Sunday 9 Feb that discussed Tramiel and made mention of the 1040ST being shown in Europe. No mention was made to the availability in the States though. A price

below - well below- $1000 was quoted though.

I know that there are lots of us anxiously waiting for it. I will pass
on any thing else I come across.

I have just been using a friend's copy of PC-Intercomm, so I don't
need anyone telling me that I deserve the mess I've gotten myself
into. But here is what happened.

I write protected the disk so I wouldn't alter anything. I then tried
to download a file from a mainframe using the kermit protocol. I got
a standard error message since the disk was write protected. I stuck
in another disk (which, of course, was an important disk) and
proceeded normally. When I exitted from PC-Intercomm, I found that
the directory of the second disk was written over with the directory
from the PC-Intercomm disk.

Using the Public Domain SectorEd program, I found that the directory
is definitely written over, but most of the text is still intact.

Now for the good part: does anyone know how I can recover random data
from a disk? Is there an easier solution than creating a directory by
hand?

I would appreciate ANY help.

Todd Fujinaka (who wishes his development package would arrive soon)

Keith:
        Read your posting about ST software in net.micro.
atari.
        Reading the atari info in the newsgroup can be very
disheartening for someone in the UK. You are lucky to get
a functioning ST here, let alone all the added extras and
software that you people from the US talk about!
        However, I've got an ST, with limited sofware
(database, word processor etc) but no compilers etc as they
are still rare. Anyway, your public domain software such as
desk utilities and applications sounds as though it could
brighten my machine up no end. Would it be possible to
get (compiled or BASIC) software from you here in UK?
As I said, things are basic here, so it would have to
be single sided discs.
        If you think you can help, send me some info
on prices etc.

                Thanks,
                        Steve Marsh.

I've just subscribed to info-atar16. I appologize if these questions have
already come up and have been answered.

First, has anyone had TOS roms installed along with the homegrown 1 Meg
memory upgrade? Does it work correctly? (ie. finds all the memory , etc.)

Second, OS9 for the ST has been rumored for a about a month now. Does
anyone know it's current status? I understand that the sysop of
CompuServe's OS9 sig will be a beta tester for the ST version of OS9.

Third, UNIX or more accurately a UNIX-alike system such as Xenix has been
rumored to be available for the 1 Meg. ST some time this summer. Can anyone
confirm or deny this? I'd really prefer UNIX over OS9 if it's going to be
available.

Thanks!

Dan,

I am responding to your note publicly; perhaps we can get some constructive
comments or some volunteers to assist in writing the new software.

I used kermit to transfer the software to my atari via a 1030 modem.
It appeared not to have been damaged in transit. You realize, of course,
that kermit has a built-in check-summing for each transmitted packet.
However, a more sophisticated check-sum built-in to the file would be
useful to those transmitting files via a non error correcting/detecting
route.

In addition to a check-sum on a per-line basis, the extra bit real-estate
remaining in each transmitted character could be used to provide extra
safety. For example, each hex value is only 4-bits, another two bits in
the same character could be used as a sequence counter, cycling 0,1,2,3,0,1...
etc... Maybe this is excessive, but it seems to me, if the bits are there
why not use them ? Another possibility is to translate each 3 binary bytes
into 4 ascii printable bytes (as in uuencode, and also MacIntosh xbin),
with a checksum every so often. This is more compact then
your current scheme. And what about data-compression (as in unix "compact") ?
Binary object code should compress at least 20% using an adaptive huffman
code. However, the level of effort for implementing data compression may be
too high.

Anyway, regardless of the encoding technique chosen, I think that two
sets of software are required. One to run on the atari and another for
the host machine. For the host machine, the software should probably be
written in C for portability. At the least, it should be able to read
a hex format file and verify that there are no checksum errors. This would
save users alot of time by letting them know the file was defective before
transmitting it to their Ataris via a slow modem. It also might be useful
to have the equivalent of hexbin and binhex running on the host. This would
be good for those who have the ability to upload and download binary
perhaps via Xmodem; the binhex'ed filed would be used only for transmission
over arpanet.

For the software on the Atari, a language faster than BASIC is definately
called for. ACTION! is probably best. Someone out there with the run-time
library could compile the program for distribution to those without
the ACTION! cartridge.

Lets hear some comments from the rest of you out there !!!

Keywords: lists sources binaries

I agree with the basic premise for being added to the ARPA mailing list,
but....
I don't know about the other groups, but there are three separate
'mailing lists' which are sort of like 'underground nets'. Two
of these lists are moderated by people on subnets which are very
difficult to get mail into. One of these is for developers, one
is for more technical information, and one is for sources, since
people have been flamed for posting sources on this group. Several
net.micro.atari readers do not have access to net.sources and get
these via the 'mail-net'. Ideally, all of this mailed information
should be posted to the net, but non-disclosure agreements and such
make it difficult to do so freely. If at all possible, please pass
info via the net rather than by mail. Does ARPA moderator forward
posted information on down the line and back up?

Also, stop flaming those who post source and uuencoded binaries to
this group. There are at least a dozen people who have openly declared
that they do not have access to net.sources. If someone wants to
forward sources to net.sources, that's ok, but many schools and businesses
restrict access to net.sources for a variety of very good reasons which
have nothing to do with access to ST source and binary code.

A good convention would be to have someone who has access to net.sources
forword to that group. If you do not have access to net.sources and
need it posted to that group, request this in your posting.

Can I assume that you are an employee of Atari? I guess that you might want to introduce yourself. I got the idea that you are maybe the answer to our dreams (an actual official conduit from Atari to the NET) If so, can we start

directing questions to you? In any case welcome! We would love to have the same sort of response that Amiga gives through their hookup to the NET. If you teach us about the ST we will teach you about Unix. Deal?

We just installed the new TOS ROM's in one of our machines. Here's
a few pointers.

* Installation is generally no problem. The worst part of the
  procedure is unsoldering the metal shield from the PC board.
  There are six ROM's to install in positions U2 to U7. Only
  U4 and U7 were silk-screened on the board, but U2 is the "top
  most" (nearest to rear) socket. A screwdriver is handy for
  prying out the old devices. The ROM's aligned quite well and
  no pins were bent out of place. In case you didn't notice in
  your haste, the indexing groove on the old chips were on the
  right hand side!

  Remember to observe good anti-static, defensive practice when
  handling the parts. Just to be safe, handle the old ROM's
  carefully in case you blow up one of the new ones and need to
  re-install.

  Overall dexterity/skill level: A little more skill than a
  Heathkit one nighter is required, but not much. Hardware
  novices should be able to do the installation themselves
  without being ripped off by a dealer.

* There were a few scenes out of the "software follies of
  1986" tho'. If TOS.IMG is present on floppy A while booting,
  it will boot from the floppy. The TOS ROM tries (and retries!)
  the floppy drive looking for TOS.IMG, DESKTOP.INF and the
  accessories. (We also jiggled the power plug loose from the
  floppy while installing the ROM's and imagine our surprise
  when we couldn't access the disk. "What the _______")

* I'm going with a small RAM disk for the PD microemacs,
  terminal emulator/FTP, and micro C shell. With the speed that
  this stuff comes up, "VAX? I don't need no stinking VAX!"

  Going to 1 Meg may be unnecessary for hardware novices or
  people like me with a neatness fetish.

Still waiting for a 2 Meg upgrade board ......

> Anyone had experience with the Haba hard disks? Are they more
> reliable than their C compiler? Any other hard disks for the ST?

Yes, the 20MB hard disk from ATARI for developers. It upgrades the
ST to a realy useful tool. The mechanical design is slightly poor
(it comes in a 12" long housing, cable connector on the back, but
the cable to hook it to the 'keyboard' is just 10" long) Inside
there is a converter from ATARI hdisk interface (sort of sasi)
to a full SASI with adaptec controller and seagate 212 harddisk.

They add the installable hard disk driver and on the hard disk
(already formated) comes a test program which reads from a file
data to be flushed on the screen (digitized from a camera in B/W)
The speed is impressing ~4 pictures/second. (the public domain
ramdisk driver was even slower <3 p/s)

Hi there, here is a thing that some of you really need:
I've written a multi-window terminal emulation for the 520 ST.
Currently, it is only supported on 4.2 BSD UNIX, because it
needs pseudo-ttys (actually, the unix side is the uw code for
the macintosh from John D. Bruner). The state is:

- Up to seven windows, 24*80 chars each (virtually)
- adm31 emulation

- Small 5*7 font so that 24*80 chars fit on a screen
- Monochrome monitor supported only

If you don't believe it, I'm editing this note in one of the 5 windows
on my screen. The other windows contain: a hack game, some 'uw' source
code, and some administration stuff. A real nice thing if you can log
in to another machine, read the source here and monitor the state of the
local net on the same screen !
Before I release it, I want to add a large font (selectable on
a per-window basis), some file transfer capability and speeeed !
In the moment it uses the vro_cpyfm() call, which is rather slow.
I think I'll write some fast routines which are optimized for the
special cases I need. This should be not too difficult, because
every transfer will be word-aligned.

Some further thoughts:
What about a local editor, which uses ed on the unix side and provides
a window-oriented interface with mouse, cut and paste and all that neat
stuff ? Possibility to run TOS programs in one window ? Graphics
terminal emulation ? Troff previewing ? Any other ideas ?

A final word about releasing:
I want to post the source to mod.sources. I will not post binaries, and
I will not send mail to anyone outside good old Germany (it's too expensive).

Since you mentioned UUENCODE/DECODE as examples of niftitude, perhaps
someone could implement those programs in Action!. Thus enabling

the encoding by an already accepted (semi)standard.

Note: UUENCODE/DECODE is currently only on UN-X machines (as far
as I know....we do NOT have it here on my VMS machine). But if it
is written in C, and someone supplies the source, it can be compiled
and implemented on almost any machine.....

> the net. Thanks in advance.

Here are the TOS ROM upgrade instructions which I received from ATARI
along with my ROMS. I have attempted to reproduce the essential
features of the one important Figure in the instructions. Please note
that I have not verified the "BOOT EPROM Version" instructions, since I
had the more common "MASKED BOOT ROM Version" which simply required
replacing the two old ROMS with six new ones.

I have had the ROMS installed for about two weeks now, and have
encountered no real problems (I have a 1 meg ST with the "six
resistors"). The only programs which I have found that don't work
properly are the PD ramdisk and fontloader programs (but M-disk works
fine). TOS can still be loaded from disk if desired. By the way,
I checked the date of the ROM version as suggested in a previous
article and got "11201985" (my disk version is dated "05291985").

                        Good Luck!
                        R. Brad Kummer   akguc!rbk

TOS ROM UPGRADE

Once plastic and shield have been removed, locate the ROM socket area of the board (left side, near cartridge slot). There are three versions of the 520ST that have been produced to date; the ROM installation will vary according to the version of the board you have, so identify your board from the descriptions below:

MASKED BOOT ROM Version == This is the most common and is the easiest to upgrade. You have this version if no jumper wire is visible along the ROM socket area and the two ROM chips don't have labels on them. To upgrade, simply remove the two existing chips by wedging a small flathead screwdriver between the chip and the socket and carefully lifting up on the chips. Once the two old chips have been removed, insert the six new ROMs as shown in the figure below. Please note that it is extremely important that each ROM be put in with pin 1 on the top right corner of the chips as shown in the figure.

BOOT EPROMS Versions 1&2 == These are very early computers which were produced before masked ROMS were available. You have this version if a jumper wire is visible running from below the socket marked U7 to the middle front of the socket marked U3 and/or the two chips in the sockets have labels with handwritten markings on them. To upgrade these versions requires soldering and desoldering, so if you don't feel comfortable with a soldering iron, it is strongly recommended that the upgrade be done at an authorized Atari Service Center. The first thing you will need to do, if you decide to do the upgrade yourself, is remove the PC board from its bottom plastic cover. Now turn the board upside down and look at the area underneath the ROM sockets marked U4,U5,U6,U7. Looking at pins 27 and 28 on these sockets you should be able to see a solder bridge shorting the two pins together; this short needs to be desoldered on all four sockets. Next, turn the board rightside up again and look between U3 & U4, U4 & U5, and U6 & U7; toward the right hand side between each of these sockets should be a cut trace. This trace normally connected all the pin 27's together, so you will need to jumper it back the way it was before it was cut. The easiest way is with three jumpers; first jumper pin 27 of U3 to pin 27 of U4; second, jumper pin 27 of U4 to pin 27 of U5; and third, jumper pin 27 of U6 to pin 27 of U7. Before finally plugging in the new ROMs, verify your work by checking for continuity between pin 27 of the sockets and A15, which can be found on pin 43 of the 68000 CPU chip (U10). Also make sure that all pin 27's are disconnected from all pin 28's.

Everone with an ST has probably figured out how the order in which
accessories appear in the desk menu is determined if the system is booted
with TOS.IMG. The ordering rule is different when TOS is in ROM. It
seems that desktop accessories appear in the desk menu in an order which
is the reverse of the relative order in which the .acc files were copied
onto the boot disk (with at least one exception). So, with lots of accessories

you can have VT52 up at the top (if you wish) by making sure it is the last accessory copied (and the FREE RAMSIZE accessory is disabled). The one exception I have noticed is the FREE RAMSIZE accessory which is always at the top (but that is ok with me since I use it all the time). Also, it seems that when Mike's RAMDISK is installed memory is never deallocated so eventually the machine just runs out of space (I haven't tried this accessory without TOS in ROM - for all I know it might do the same thing in that case - it seems to me that if the contents of a certain key memory location were changed periodically one could probably keep available memory from slipping away (but I haven't looked for that location yet)). I have to use Mike's RAMDISK for the moment since the 1040 PD RAMDISK doesn't work at all with TOS in ROM. Also, the PD Fontloader does not seem to work. However, everything is back to normal if you put the TOS.IMG file back on the boot disk.

I have a 1200XL that my wife and daughter use for games and word processing; we've got the micro, a cassette, and a printer (no disk drive or modem as yet). Is there a VT100 terminal emulator available that would permit us to interface on full-screen cms with my university computer? If so, where could I get it, and what additional hardware would I need? Please reply to me directly--I'll summarize answers to the net. Thanks.

I am thinking of writing some programs in ACTION! which require me to
interface to the cartridge in a really weird way. Is it possible for
an ACTION! program to invoke the compiler (i.e. instruct the cartridge
to read in and compile a new file) possibly wiping out the first program ?

I am running VIP on the standard 512K 520ST and have seen similar problems.

1) On very rare(albeit important) occasions I have lost my spreadsheet to
a System 2 message. It always seems to be related to printing somehow as
I have just recently done some printing.

2) I am using a printer that does not understand Epson escape sequences
so if VIP depends on an Epson, that may explain some of my problems.
Basically I am missing numeric data if it is in the first column and
any labels that exceed the column width will offset the data to the
right of them the same number of spaces. This is a well known bug
which has been reported.

Computer-Viruses: Help needed !!!

Please don`t mind for posting my request into this
notefile.

I have been searching for any kind of literature
concerning the subject of `computer viruses` for

three weeks now and my results are rather poor.

I only found 2 interesting entries in the databases
locally available. Because I intend to get a Ph.D.
in protection mechanisms against computer viruses
I really have a big need for more references and
hints to get.

So, if anybody out there in the net does know something
about the stuff, please give me any kind of information.

I`m also interested in getting contacts to others
working on the same or similar subject.

If there will be enough feedback I will summarize the
replies to the net.

Thanks in advance

There is a program available that loads the time and date registers
in the 520 ST from the Prometheus Pro-modem. It is on Compuserve
ST SIG DL2 and it is called protim.prg. I have used it for a couple

of days now, and although it doesn't work from a form called auto
(I don't know why), it works fine if you just execute it from
TOS. If someone really wants this program and doesn't have a
Compuserve account, write me and I will try to work out
something to get the program to you.

By the way, I have ordered Megamax C and when I get it I will post a
review to the net. One of my first projects will be an Epson.prg
program similar to the public domain Epson.com program for the
IBM. If any one knows how to write to the printer and accept
data from the key-board in C I would be interested in hearing
from you.

I called up atari and they stedafastly refused to give a reason for the
delay only that it was not ready but would be ready on the 15th of Feb.
Previously I had only heard throught the dealer that it was `about a week
away' (four weeks ago and every week since). I would love to find out what
is delaying them.

Neil,

Hi!
Great to have Atari on the net! Rumors fly fast and furious around here. Hopfully you will be able to improve the accuracy of net information. Can you also supply technical information (hardware/software) when specific questions are asked about the 520?

John

I've been using one for a year or two now, mostly with Atariwriter and it
is slooooooow. Also mine has the charming habit of stopping and repeating half
a line occasionally. Not so much fun when you're trying to print out a novel.

Perhaps you, and a lot of other people also, could start by:-
1. Learning to spell
2. Learning to type, or at least to use an editor.

(Once upon a time I started to compile a list of the most common
spelling errors. However, it depressed me so much that I soon gave up.
Note that I have not even asked that people write proper English/American)

~~~~~~~~~~~~~~~~~~~~~~~~~~\ lineater, \~~~~~~~~~~~~~~~~~~~~~~~~
~~~~~~~~~~~~~~~~~~~~~~~~~~

this is a program i wrote when i was first learning the ST, it gives
an ascii description of a resource file created with the resource
editor. To use it you need both the .C and .H files from the editor,
these are gotten by (if memory serves me correctly) selecting the
'save source' option from the menu. You should replace the #include
for flibs.h and flibs.c with your own and recompile the program. It
was written to run under 4.2BSD but should run on the ST. Please
send all bug reports to me, flames to /dev/null.

```
#include "stdio.h"
#include "obnames.h"
#include "portab.h"
#include "obdefs.h"
/*************************************************************************/
/*                                                                       */
/* INCLUDE the 2 files created by saving source from the resource        */
/*  editor after this comment. For example:                              */
/*                                                                       */
/*************************************************************************/
#include "flibs.c"
#include "flibs.h"

main()

{
     int i,j,k;
     char buf1[24],buf2[24],buf3[24],buf4[24];

I have just purchased the TDI modula2 for the Atari ST, and I was was wondering if anyone has written a decent modula2 debug package that they would be willing to share? I am new to modula2, so if there are debug tools available that I don't know about I would be interested in hearing about them.

The recent posting of cpm80.tos is not public domain and should be
removed from any archives, public or private.

As several posters have noted, there is a copyright notice in the binary.
Atari here in the U.S. does own the rights to this software, and is
planning to release a working version here, for sale. They did not
comment on Uwe Hoch's claim that Atari Germany released it PD. They
did state that the German version is preliminary, and will not work
with rom tossed machines.

WHAT BLITTER????? Somewhere in the documentation I saw an interrupt
vector for "gpu blt done"...but nothing else! I can't believe there
is special hardware for bitblt on the ST, since vro_cpyfm() is
too damn slow(*). Unless, of course, the "blitter" is only useful for
doing no-skew, whole word transfers...

Please please please tell us more. Maybe you could even fill us in on
how to do bitblt from the line A vector (since my documentation (and
others) were missing the last n pages of the "Long Awaited Line A
Document").

Thanks,
Jan Gray Looking Glass Software, Waterloo Ont. (519) 884-7473

p.s. Are you *the* l. dyer who wrote the BIOS, etc (or at least had his
name on the listings?)

(*) That is, for doing large image processing tasks like "spreading" the
screen, running life on the whole screen etc. (BTW, can anyone beat
400,000 life cell-generations per second on their ST?)

I have a TRAK AT-D4 disk drive. This is the double density,
double-sided drive that pretends it is two drives, using the

second side written backwards. TRAK includes a slave port
on the back to control other drives. I would like to know
what drives will it control, and what protocols are available
on the pins/edge-connector.

Part 2: I also have an old(?) drive out of an APPLE LISA.
These are better known as APPLE's boondoggle. This is APPLE's
own wierd design for double sided disks, with 4 R/W slots on
the disk (the two heads clamp onto the disk 180 degrees apart
from opposite sides, with each head having a felt pad opposite
it). I think these would be fun to play with. Has anybody done
anything with these before???

Thanks, I eagerly await any info....

In Byte (Feb. 86) there is mention of a pd ram disk on BIX (article number
54 in atari/tech.st), which should also be available on compuserve and
on a number of other bbs. If any one has a copy (source please) of this
ram disk (or any other one), could they please post it to the net.

Yep. Use stamp pad ink. DON'T USE DRAWING INK. I know this sounds obvious, but I trashed one roller and had to clean off the barrel (let's have a barrel of fun...oops sorry.) Silica Shop in Britain advertises them, but I suspect that they don't exist, since SS never have them.

I've received several messages from netters regarding various weird behavior by the 1027. The most common complaint is that it stops, dead, in the middle of a print, often needing to be repowered. As for my own 1027, I've noticed that when I use DOS2.0S to copy a file to the P: device, the printer will always drop dead several lines into the file; this is relaibly repeatable. However, when I write a BASIC program which feeds test lines to the printer, I can not get it to die. I seem to recall reading in one of the Atari magazines that the printer problem was a known software "feature"; something having to do with a kluge that would keep the 1027 from overheating by forcing it to take a rest once in a while.

Does anyone else have any information to share regarding this problem ? I think I've seen on Compuserve a patch for AtariWriter which is supposed to rectify this problem.

> 1027 printer wierd behavior ... stop in middle of print ...

I've had the same problem with my 1027 on my 1200XL using Atariwriter. If I
wait several minutes the print will continue. We often used break to kill the
print of the page and start over instead of waiting.

The problem vanished when the "Translator" program was booted first. I have
never seen the problem while using the 1027 with my 800. Sounds like a
bug in the XL operating system(s) ROM.

I am contemplating building some hardware that uses the cartridge slot
on the ST. The hardware would have memory mapped I/O. If anybody has
successfully tried this, I'd like to know how the control signals in
the cartridge slot function. Is it possible to read from AND write to
memory locations in the ROM memory space? How?

Thanks.

Never heard any more about this. Since I have an Atari and an 820-II I am
interested.

Denny

TDI claims that they're working on a symbolic debugger. They say to expect
it in a couple of months... (wish they'd fix the editor first...)

If it is a color monitor it should work just fine.

If it is a monochrome monitor, you will probably have to
re-tweak the vertical and horizontal hold controls to lock it in, and you may
well have to make some changes to the sweep circuits both to lock it in and to
get a full-sized picture with the right aspect ratio (horizontal to vertical
scale factors).

However, I hasten to add that I have never tried this and don't even own an
ST (yet). The main problem is that the ST expects a monochrome monitor to
run at a 70-Hz frame rate, non-interlaced, and to have 640 by 400 pixels.
Standard monochrome monitors run at 60 Hz and I'm not sure of the screen
resolution. The 400 should be no problem, as this is an "analog" quantity.

But the number of lines is not, and there may be a problem of "folding over"
of the picture. Also the geometry may not be right unless you change the gain
of one of the sweep channels.

If you think I sound like I know what I'm talking about, don't be fooled.
Find somebody who really knows what monochrome monitors are all about.

No, no, no! If I recall correctly, the original requestor said that he had a color monitor with *COMPOSITE* input. Unless the new STs also have composite output, you may have to build a rgb-to-composite circuit. Now there I can help you, if you like.

DD A COLD START RESET TO YOUR XE

After I got my new 130XE, I began to get a little frustrated by the ram chips in it. In order to do a cold start, I had to leave the machine off for at least 20 seconds. This is a *real* long time.

I was convinced there had to be a better way.

First of all a little history about what causes the problem. When Atari switched to the XL/XE line of computers, they changed the reset button to do a hard chip reset instead of an interrupt like on the old 800's. This means that every time the reset button is pressed the 6502 does a reset and starts over. The software must determine whether this is a cold start (power up) or a warm start (reset button). It

does this by checking for a signature in the ram. On the XE there are three bytes $33D, $33E, $33F. If these three bytes are intact ($5C $93 $25) then it does a warm start. If any of them are wrong then it does a cold start.

The same day that I picked up my 130XE, I ordered the OMNIVIEW XE operating system from CDY. This OS gives you several advantages.

1. It does away with the need for a translator disk. It looks like the old Rev B operating system.
2. It gives me an 80 column mode for some applications.
3. It reverses the effect of the option key at coldstart.
4. It gives me ramdisk capability with any DOS.

This OS only uses the first byte of the signature ($33D).

I decided to fix my OMNIVIEW XE OS first.

You will need access to an EPROM burner and a 27128 EPROM to make this fix.

The fix.....

My fix involves 'stealing' the reset vector and checking the keyboard secondary buffer. This is a byte at $2F2 where the keyboard handler keeps the last button press to see if it should start auto-repeating on the next key stroke. I decided to use 'shift esc reset' as my cold start method. If the byte at $2F2 is $5C then the last key press was the 'shift esc' and I trash the byte at $33D and let the system continue with a normal reset. This will cause a COLD START without touching the power switch.

The program.....

```
     LDA $2F2   load the last key buffer
     CMP #$5C   check it for 'shift esc'
     BNE EXIT   branch if it isn't
     LDA #$00   load a zero
     STA $033D  trash the signature
EXIT JMP RESET  continue with the system reset vectors
```

I made this change on the OMNIVIEW XE rom from CDY first. These are the changes for the OMNIVIEW XE rom.

********** DAVID YOUNG are you listening. **********

The changes....

EPROM ADDRS	OLD	NEW	
3FFC	29	20	power up reset vector
3FFD	EF	E9	power up reset vector
2920	44	AD	
2921	61	F2	
2922	76	02	
2923	69	C9	
2924	64	5C	
2925	20	D0	
2926	59	05	
2927	6F	A9	
2928	75	00	
2929	6E	8D	
292A	67	3D	
292B	20	03	
292C	CF	4C	
292D	CD	29	
292E	CE	EF	

These bytes were used for Dave's title 'David Young OMNIVIEW XE (C)1985'. Sorry Dave, but this was the only safe place I could find!!!!

If you boot without basic his message will be messed up.

NOW THE XE......

There are about 30 bytes of $00 in the rom at address $24A0. This area was reserved for jump vectors, but was never needed. The XE OS does a rom checksum during power up. So I changed that routine so it will always pass the check.

This fix should also work on the XL series, but you may have to find a new location for the code.

The changes....

EPROM ADDRS	OLD	NEW	
3FFC	AA	A8	power up reset vector
3FFD	C2	E4	power up reset vector
3F90	38	18	defeat the rom check
24A8	00	AD	
24A9	00	F2	
24AA	00	02	
24AB	00	C9	
24AC	00	5C	
24AD	00	D0	
24AE	00	05	
24AF	00	A9	

```
24B0     00      00
24B1     00      8D
24B2     00      3D
24B3     00      03
24B4     00      4C
24B5     00      AA
24B6     00      C2
```

If you have both systems installed with a switch to select one of them at a time, you may want to make an additional change. Right now both systems use $5C for the first signature byte. You might change one of them to use a different signature byte. This would require finding all the places in the OS that it checks this byte and making the neccessary changes.

Once in a while, if your system is 'locked-up' it may take two attempts to get a cold start. It seems the first attempt gets the interrupt system working, then the second attempt does the coldstart.

NO MORE FLIPPING THE POWER SWITCH FOR ME.

Hope this works for you.

[Where do all the eaten lines go?...]

I got a call from a friend of mine last night who told me he's thinking
about buying a computer to use for his small business and is looking at the
ST. Now, I've been away from the microcomputer world for a couple of years,
and all this sort of took me by surprise -- I spent last night going through
net.micro* trying to catch up. What I'd like from all you wonderful netters
out there is whole bunches of information about what's what: What's the
poop about the ST line? Is the "development kit" generally available, or
do you have to be a development house? What's being sold to the general
public -- everything? How good is the 520ST? What about the 1040ST?
Availability? Accessories? Software? What's the TFM machine (it was
referenced in an article wrt UN*X on an ST ROM)? What's the source of the
heated debate over Amiga vs. ST? What's the 'info-atari' user I keep seeing
on a lot of the postings? Is Atari on Usenet now? Is there truth in the
UN*X-for-the-ST rumor? What would be the anticipated cost of a 1040ST with
1Meg of RAM, a 10Mb hard disk, monitor, and printer? Recommended dealers
in the L.A. area? What's the meaning of 42? (Just kidding ;-))
Anyway, you get the idea, I hope. Please mail any responses (gee, I *hope*
there are responses) to:

       (east coast): ihnp4!allegra!ima!ism780!dianeh
       (west coast): decvax!vortex!ism780!dianeh

Thanks in advance for all your help,

Diane Holt

Try this. It is supposed to become a directory fixer for DD diskettes;
that is only part started, but density detection and switching are in there
and they worked.

MODULE; DENSITY ---------------------
; From Mark Reed, on ACS bulletin board. Mods by B. Langdon
;This program changes the density of a PERCOM-compatible drive from
;single to double density and vice versa.  It also displays the values
;in the drive option table before and after the change.
;Note that by changing the Set_DENSITY() procedure you could configure
;the disk controller to handle a double sided or 96TPI (quad density)
;drive, assuming your controller can handle these drive types.
;(The PERCOM RFD-1 and ATR8000 can, the TRAK, INDUS, etc. can't)

     Speedscript is definitely NOT public domain. It is copyrighted by
COMPUTE! If you want to legally own a copy, first you must own an issue
of COMPUTE! in which Speedscript was published. Then (so you don't have
to type it in or pay $12 for a disk) find a friend who already has a
copy and copy it.

----
i.   The C-compiler and pre-processor (cp68.prg, c068.prg, c168.prg)
ii. The linker and relocator (link68.prg, relmod.prg)
iii. A utility disk (dump68.prg. size68.prg, command.prg, etc.)

Are these the same as CP/M 68K counterparts (but renamed)?
Is it possible to execute CP/M 68K programs under TOS?

     Thanks,
     Jack Bicer

I think Atari should tell their German division about that. Today I got
two good news:
1. Atari Germany has released another, newer version of CP/M-80-Emulator
as Public Domain.
2. Today I read in a St magazine here about an interview with Alwin Stumpf
(President of Atari Germany) and Dr. Hans Riedl (Chief of the software
division), that the Emulator is distributed FREE!

If anybody thinks, that I havn't done right distributing the emulator,
I'm willing to send him the written permission of Atari Germany, in which
they state, that the emulator can be distributed free to any end user
(Of course it is in German language). But please send a return envelope
with postage.

Another thing: Before anybody sends me mail or asks via the net:

I DO NOT (!!!) POST THE NEW EMULATOR TO THE NET. ALSO I DON'T SEND IT BY
POSTAL OR E-MAIL TO ANYBODY. SO PLEASE DON'T ASK. I WILL NOT EVEN ANSWER
TO ANY QUESTIONS.

But I have a hint: If anybody wants the emulator, take a ticket for an
aeroplane :-) and visit good old Germany. Then go to an offical Atari
dealer, put out a 3.5 inch floppy and get the emulator copied. If you want
any address of an Atari dealer here, I will send it to you. The best way
is, I think, to fly to Germany via Frankfurt. About half an hour from the
air base is the German division of Atari. Go there and get your copy of
the emulator. :-) :-) :-).

In the meantime, I think you should take the emulator from your PD archives
and wait what Atari will do in the future.

Does anyone know how to convert STwriter files to ASCII? I have a series of Gem Tutorials (I think that they originated from Compuserve) that I would like to post in net.micro.atari, but they're in that strange STwriter format.

In the mean time, here's something useful; an Index to the GEM manual that you get with you ST developers kit or your IBM Gem developers kit.

GEM SYSTEM SOFTWARE "EASY REFERENCE GUIDE"

Preliminary Version B0.2 (01/28/86)

Provided by
Digital Research GEM Programmer's Support

This index is provided to aid software developers in referencing the proper source for documentation of GEM System Software functionality. The functions included in this list are the sum of GEM functions referenced in any piece of documentation plus those referenced in the source code bindings. The page numbers refer to the GEM System Software manuals, First Edition April 1985. This is an IBM specific document at this time.

I've been (trying) to use VIP for a home finance system with some
pretty bizarre results. I've got a fairly small (200X50) worksheet
and the 12/18/85 update of VIP. I'm using the TOS system disk as is
(standard desk acc. files) and a 1 meg ST without TOS ROMs. /WS tells
me I've got 288K of available memory after the worksheet is loaded. Now
here are some of the nasty things I see:

1. Lots of "2 system error" and "3 system error" messages, garbled
    worksheets (things moved around in random places), lockups and
    mushrooms especially when doing CALC after a few items are added
    to the sheet. This also seems to happen when doing /WIC or WIR
    commands. After the system errors occur, nothing is recoverable.
    I assume these errors are processor exceptions, does anyone
    know what the 2 and 3 system errors represent?

2. Loss of data and column skewing when doing range prints. I'm using
    a Gemini 10X printer.

Problem 1 has rendered VIP useless to me. I don't want to use up
any of my customer service allocation on what are possibly bugs in
the program itself, so please let us know on the net if you have
encountered similar or other problems. If you have a system setup
similar to mine, have beat on VIP to some extent and DON'T have
any problems, please send me mail or post this info on the net.
Thanks!

/* Written 2:34 pm Jan 23, 1986 by MRC%PANDA@SUMEX-AIM.ARPA in net.micro.atari */
I am really getting sick of the childish messages on this list that make
fun of serious concerns related to the ST's marketing.
/* End of text from net.micro.atari */

I have yet to see a message displaying serious concerns about the ST's
marketing. What I *have* seen are "Nyaah, nyaah"-style messages from
folks who seem to feel insecure about their choice of computers, and thus
look for any imagined opportunity to tear down the 520ST, claiming that
any inexpensive computer is a "toy," that nobody will write software for
a computer that doesn't cost too much, and posting innuendos about the
520ST's or Atari's alleged imminent demise. Up until very recently,
nobody has bothered posting any of the various articles describing
Commodore's financial troubles to net.micro.amiga. I know I've refrained
from posting items I saw a while back in *Info World* about delays in
software development for the Amiga.

Have fun, folks; I'll be back when OS-9 is out for the 520ST. With luck,
notes might have additional filtering capability by then. Even better,
people who seem less interested in technical matters than in bolstering
their egos may go away.

>
> /|\/|\/|\/

by Fred Fish, I am organizing a collection of public domain software
for the Atari ST machines.

THE LIBRARY

I am collecting and organizing programs which can be freely copied and shared, including teaching aids, utilities, demonstrations, and applications which are of use to programmers/developers, hobbyists, and members of Atari Users Groups. Programs will be grouped so that those logically related appear on the same disk, in as much as this leads to efficient use of storage space on disks. Whenever possible, the source code as well as object code for the programs will be distributed. To the extent that time permits, I am writing brief critiques/bug reports to accompany the software collected (as well as ascertaining that the effects of each program's execution is benevolent!). In addition I plan to author some tutorial programs on various aspects of programming for the ST and include these in the library.

SOFTWARE AVAILABLE

I have the usual demos of color and monochrome pictures, some games, freebie text editors, graphics editors, and ramdisks, miscellaneous utilities (such as a program to be placed in the Auto folder which queries you of time and date at boot-time), a dumphex utility, and several desk accessories. The above programs account for about 5-6 double-sided disks worth of software which will be distilled to make up the first 3-4 disks I distribute. I am also down-loading (and converting to the ST) programs from Net.Sources and (indirectly thru a friend) from CompuServe. In addition, I am taking programs from the Amiga library (many of which use only the standard C-language interface) and porting them to the ST. (Of course some of these programs depend upon the hardware/operating system specific to the Amiga and which will not be ported.) Likewise, there is a wealth of public domain programs for the Macintosh which could be converted to GEM. In the absence of objection, I'll post on this bulletin board a listing of the contents of each disk as it becomes available.

OBTAINING DISKS

I want to distribute the disks first to organizations and people who are willing to share what they get from me with friends or user groups. I am a member of the ST Developers Forum (a developers group in the San Francisco Bay Area) and will be sharing disks with other members of that group and with members of BAAUG (Bay Area Atari User Group). As has been noted many times, in order to ensure success of the ST, the software vacuum must be filled quickly, and for that to occur, aids for programmers should be readily and inexpensively available. So I would especially like to hear from members of other user groups who would make these disks available to their groups.

If you need a disk NOW, or can't find copies of these disks locally (which I hope will not be the case in a couple of weeks!), I will mail them directly to you for the cost of medium, mailing costs, photocopying, and misc expenses. The charge will be $10 for each double-sided (Sony) diskette 80-90% full of public domain software. Normally I will distribute the software on double-sided diskettes. However, since some ST owners have only a single-sided drive, I will also distribute the software in each double-sided disk as two single-sided disks and charge $12 for those two disks. If you make an order and send excess money, then I will apply the excess to the next disk and mail it to you when it becomes available. (If you're interested in "just demos" or "just utilities" or whatever be sure to tell me.) As stated above I have 3-4 disks almost ready to go, with roughly 1 1/2 disks utilities, 1 1/2 disks graphics demos, and 1 disk applications.

Finally, I am eager to hear from other programmers who wish to contribute to this library software they've written or ported. There are thousands of public-domain programs from other computers which could be adapted to the ST, but of course I don't have time to convert all these (and its more fun to write original software anyway), so I solicit aid from others in making available (public domain) software which they feel may be of use to fellow ST users.

I guess that's everything except ways to contact me if you want to share software, get disks, or to suggest ways to make this operation run more smoothly:

Here are definition and implementation modules for bios calls for use with TDI's Modula-2. I found these on CompuServe. I have almost completed a similar interface for xbios calls, that i will post shortly.

```
#!/bin/sh
# This is a shell archive, meaning:
# 1. Remove everything above the #!/bin/sh line.
# 2. Save the resulting text in a file.
# 3. Execute the file with /bin/sh (not csh) to create the files:
#    bioscall.def
#    bioscall.mod
# This archive created: Mon Feb 10 03:10:05 1986
# By:    Jwahar R. Bammi ()

If I remember correctly, making a drive change densities to match the
disk inserted is as easy as reading sector 1. Then you need only do a
status call to find out what the density is.

I am not one of the 'cretins' etc., but I think that the reason that
they post the requests to the newsgroup is that they can't figure out
how to mail the notes to the ATARI-INFO-REQUEST. Most of these people
are probably fairly new to the USENET. Why don't you publish an article
on how to find out the path to the ATARI-INFO-REQUEST.

ARRGH!!

I was happily reading info-atari and saw someone quote virtually the entire
text of someone else's message, then snidely suggest:

>Perhaps you, and a lot of other people also, could start by:-
>1. Learning to spell
>2. Learning to type, or at least to use an editor.

FLAME ON!!!

First of all, this kind of trash is uncalled for on the net. It serves no
purpose whatsoever.

Secondly, this poster has no idea with what situation the original poster
was struggling: I have done my share of time working on systems that only
had line oriented mail programs on terminals where the delete key was
immediately adjacent to the line-feed key (like the one I am on now).
I have made my share of spelling errors in mail messages, and I KNOW how to
spell quite well thank you.

FLAME OFF...

To the original poster, who indicated that (s)he was new to the net and
inexperienced: welcome aboard, and remember that not all of us are snide.

Non carborundum illegitimati.

Does anyone know the real truth on the C compiler switches. They
certainly don't seem to correspond to the ones described in the
developer's manual (or have I missed them somewhere in the 12"
of paper?). Specifically, what does -f do (it was in their sample
c.bat). The manual says -d is used to include source line numbers,
but I get them without the -d and would like to turn them off.
(Look at the .s in case you haven't before - probably 25% of the
file is filled with line numbers).

Any help would be appreciated.

Now that there is an INFO-ATARI16, it would seem to me that when a posting
is ST specific, rather than of general interest to ALL atari owners - or
at least mixed - that it should be directed to the new list. Those who
insist on cluttering up the net with inappropriate postings rate in my book
right along with the cretins who were perpetuating the ad-nauseum exchange
about mac vs. st vs. amiga. Likewise, postings which are 8 bit specific -
no general interest material - belong at info-atari8.

Keywords: terminal, termcap, UNIX, Action

I have sent the source, termcap and documentation of ACSTERM to our
moderator for possible inclusion in the archives. I will also send it
directly to anyone who requests it. It is about 39K bytes.

ACSTERM is a terminal emulator for the Atari 800, 800xl, 1200xl, 130xe.
It provides cursor motion, insert, delete, etc. The 'termcap' file tells
UNIX systems how to manipulate your screen. With 'more' and screen editors
like 'vi', this does near the best that can be done with a 40 column screen.
     The tilde and curly brace characters are provided using a redefined
character set; ^M etc. have their usual ascii meanings.
     ACSTERM was written by Clint Parker, author of the Action system.
All sources are in the Action language.
    As downloaded from the bbs he maintained, you must use the Action cartridge.
Here there is also a modification that compiles with the run-time library

to make an executable file that needs no cartridge.

     NB! R-Verter owners: The RHAND1C modem handler converts tilde and brace characters. Since they provide the source, I deleted those parts. I also cured occasional glitches it had running full tilt at 9600 baud, and improved its handling of S/Reset. As that software is copyright, I can't upload my version. However I am willing to upload a 'diff' file that shows the changes I made.

     These are the files:
TERM.DOC read this
TERMCAP.ACS   get this into your UNIX
TERM.AC0 Compile this file.
TERM1.AC0 these files will
TERM2.ACT be INCLUDEd
TERM.AC2 My modifications
TERM1.ACT of TERM, TERM1.
BLKIO.ACT CIO caller and fast I/O.

I wrote an XMODEM module but never got it integrated into ACSTERM.

    This is an archive made with the UNIX utility 'ar'. Its first line is:
        !<arch>
For some reason the ! causes 'more' to think it's not an ascii file; but
'cat file | more' works, as does vi.
    If you don't have 'ar', split it with a text editor.

Summary: S.A.M.

In article <8602051021.AA08835@ucbvax.berkeley.edu>, godden@GMR.CSNET (Kurt
Godden) writes:
> 1. Before I order back issues of ANTIC with S.A.M. programs in them:
>   Is S.A.M (software automatic mouth) a published program in ANTIC,
>   or is it commercial only, and the ANTIC programs just utilities?
>
> 2. I am going to type in (!!!) Speedscript 3.0 from May 85 Compute!

S.A.M. is a commercial product, and I don't believe it was ever
published in ANTIC. I have seen several S.A.M. utilities appear
in ANTIC over the last 3-4 years. I did purchase S.A.M. a few
years ago and would like to give you this warning. It comes on
a highly protected boot disc; you use it by booting S.A.M. and
then running your BASIC program that writes via S.A.M., thus
producing voice. I bought it so that I could produce software
for my young daughter to use even though she could not yet
read. When I got it and found out she would have to boot the
system with one disc, swap discs, and enter a command(s) to
run my program I knew S.A.M. would not meet my needs. It has
sat in my cabinet mostly unused since then. There was a utility
in ANTIC that enabled you have S.A.M. read a program to you.
This has been useful when I have typed programs in from magazine
listings, in that it makes it fairly easy to check my typing.

With regard to typing in Speedscript - I have just replaced
LETTER PERFECT with PAPER CLIP. It is available under $30 from
discounters and seems to be a very good word processor.

Sorry for the length of this.

The CPM-80 emulator may not be PD. But in the recent (Jan-Mar) Issues
of Dr. Dobbs Journal is the 68000 source for a program to emulate
an 8080 (w/ some Z-80 support). The article is in the Jan issue,
but the listing is continued through three issues due to length.

This is NOT a full CP/M emulator w/ CCP etc. but it DOES run CP/M
programs on your 68000 machine. I do not know which machine it
was originally written for. Good luck,

The INSIGHT ATARI column in COMPUTE! magazine a couple of months back
was talking about the SIO & CIO functions & how to use them. This i
included a little CONFIG program in basic to check the format of disks,
a small change would enable you to change the format of the disks.
Caveat: The disks marked by Atari do NOT follow the standard started
by (I think) Percom. If you have any other drive, it should work.

I just tried to post a message but have reason to believe I botched it.
In my rather lengthy non-transmission, I asked for any relevant information
from anyone doing developement, primarily with Megamax C but all info is
appreciated. Send responses to me here or to:

Sam
1241 Monte Vista
San Luis Obispo, CA.

We got our TOS in ROM but without instructions. I don't know who else
has had this problem but I suspect a number of people have or will.

Therefore, I am requesting that someone with the instructions post them to the net. Thanks in advance.

****
ITS HERE, ITS HERE, ITS HERE
THE GEM PROGRAMMER'S MANUAL IS IN THE BOOKSTORES!!!
****

Hi everybody, get excited! I stopped in a local bookstore (Dalton's) yesterday and they had the GEM Programmer's Manual by Abacus. After skimming thru the book, I highly recommend it to the people that have HIPPO-C or want to program in assembler. The book seems to be very thorough in describing the VDI and AES functions. I compared it with the HIPPO-C listing of VDI and AES functions; the book describes about 75% of the VDI functions and about 120% of the AES functions that HIPPO-C supports. And there are plenty of good example programs in both C and assembler.

The book fills in some of the missing documentation that is required for really programming the ST. I was totally amazed in what GEM will do for you. For example, GEM already has built into it the 36 different pattern fill designs and all you have to do is ask for them. Another example is that it also has special graghics text such as bold, italic, outline, underline, etc. and you can get combinations. Yet another example is that GEM will draw boxs, circle, ellipses, arcs, ellipical arcs, and etc. for you and fill them in with any color pattern you want. You can also generate your own pattern designs. I am very excited about this book and the information that it has given to me. So far I have been blind in trying to program the ST and now I have color!!!!

This book is even better that their ST INTERNALs book, so go and get your copy NOW! I have mine.

I newgroup'd net.micro.atari8 and 16. They will replace net.micro.atari.
This is being done in accordance with the user poll I took several months
back. It has taken this long to get all the people involved in the change
together, and will take a few more days until the connection to ARPA is
set up. Until then, please don't use the new groups or you will not
reach ARPA readers. I'll post when it's connected.

If everything goes according to plan, net.micro.atari will eventally be
rmgroup'd.

Please mail me flames instead of cluttering up the group, there's time
to post later if I turn out to be unreasonable.

I guess its time to throw in a few comments about my experiences with the 520 and reply to a few articles I've seen on the net.

First, I think a person can do quite useful development work on the ST and pay in the $1000 to $1200 range. The question is how. I have a 520 ST with color monitor. I purchased the OSS Personal Pascal package and the book on Atari 520 Internals (total retail price is around $1100 for computer, software, and a good reference manual). This adds to the basic hardware an editor, a high level language compiler, a linker, and a description of the hardware and how to use GEM and the BIOS for those things outside the Pascal definition (e.g. how to determine if a character is waiting at the RS-232 port). I won't be so bold as to claim this combination (Pascal+book) is as good as the developer's kit, but it is a good substitute at 1/3 the price.

On the plus side, it has very nice libraries for windows, dialog boxes, menus, etc. and a simple interface for accessing GEM and the BIOS directly (whose calls the book documents). The compiler is quick and after one deletes all the demo files from the working disk, there is room to create and run small to medium size programs (<500 lines). I have called OSS for some support and they do seem to know their product and are helpful. The language implemented does conform closely to the ISO standard with a few welcome extensions (it is actually very similar to UCSD Pascal), so portability isn't a real problem.

On the negative side, there are the limitations of Pascal (you just can't do everything with it that you can with C or assembler, but that discussion goes in a different news group). It would be nice if the package used less disk space (i.e. more room on disk for creating programs), but the separate compilation facilities help. Plus, when I get TOS in ROMs (that is a hint for my dealer), I plan to install a RAM disk (first shot will be the 90K public domain version). That will ease the disk problem and speed things up. In the future, I will install the 1MB upgrade and use a full 360K RAM disk, which could hold the Pascal package. The other thing lacking is utility software. But there is a lot of public domain stuff, both on the net and from magazines (Dr Dobbs Journal had a C listing for XMODEM last summer) and User's groups.

Thus, by trading some of my experience and time (converting code from C to Pascal is a pain) for money, I have thus far been able to keep the cost down and utility high.

From: "...decvax!decwrl!rhea!Squirt!McCamy"
Merrimack, New Hampshire

I recently purchased the 520 ST. I'm new to this user group
and have some questions.

1. Does anyone have experience with the Modula-2 software
    developed by a British group?

2. What does one get in the development package offered
    by Atari for $300?

3. I did not receive BASIC with my computer, Atari is
    sending it to me. Is this a powerful implementation
    of BASIC or would I be better off with another
    language/software that better utilizes the capabilities
    of the 520 ST? I want a development language that allows
    structured programming and taps the powerful graphics
    capabilities of the 520 ST.

    I've never used 'C' before, does anyone out there recommend
    it, and why?

    Sorry if I've rehashed old questions.

I have the new version of SynCalc and have had no problems loading it on my
1050. I have a 256K XL (ala CDY) instead of the 130XE, but I don't think
this should make a difference. My drive runs at about 288 give or take a
few RPMs, sounds like you just got a bad copy. I suggest returning it, if
you still have problems I believe Synapse will exchange it for one that
works.

Good luck!

I've just gone through some efforts to become familiar with Atari-oriented
computer magazines, and the following comments summarize my impressions.
Bear in mind that I have only seen a few issues of most of these magazines,
so my comments could well be unfair to some of them.

BYTE, Antic, Analog, and COMPUTE! all have run articles on the ST. BYTE for
January '86 and COMPUTE! for October '85 have "product descriptions" on the
ST. Antic and Analog are entirely devoted to Atari products and have
significant sections devoted to the ST. COMPUTE! is fairly evenhanded amongst
the small personal computers including IBM, Apple, Commodore and Atari, but
still has devoted significant efforts to the ST (as well as the Amiga).
COMPUTE! has in the past provided much excellent information in book form, and
I suspect that they will soon carry the tradition forward to the ST products.
I have been much impressed with their virtuosity on the 8-bit Ataris, so I
suspect that they will continue to be one of the better sources.

Antic seems to be more game-oriented than the others. Depending on your interests and applications, this may be good or bad.

Analog seems to have the most complete selection of software and accessories specifically for Atari products in its advertising. It seems to be more "technical" than Antic.

I suggest you browse at your friendly local newsstand (surely in Berkeley, CA there are newsstands that cater to computer freaks!!!) and see which one(s) you like best. I hope you will get other comments which add perspective and balance, as I am acutely aware that my impressions are based on a very brief look at these magazines.

Compute! books publications is already advertising a book for the ST
and one for the Amiga. I don't know how in-depth theses books are though.

I don't see much said anywhere about the sound on the atari ST... could
anybody tell me what the quality is like???

Also, i would like to know how many colors are available in 640x400
mode and are there any sprites, or player grapics supported???

Thanks in advance...

   Unless I'm mistaken, that's merely a convention. The display memory
can be anywhere (subject of course, to the usual alignment restrictions).

>Also, you'd have to find a place to put the
>additional memory chips without destroying the RF shield - a packaging
>nightmare.

  Granted, a problem; but there are a *lot* of 800XL's out there with 256K
and 512K already.

>Sounds like an awful lot of work to me, and when you finished up you
>would still not be able to run ST programs because of instruction set

>Unless you want the experience of tearing apart your 8-bitter and
>learning something, I think you'd be further ahead to buy a new ST. (Of
>course, those of us who use our 8 bitters for word processing, game
>playing and bulletin-board-calling don't really need 16 bits anyway...)

   I think you missed the point. The chip would be faster if only you
take into consideration the fact that it could do memory transfers and
arithmetic in 16 bits. I once attempted to alter the public domain
Small-C compiler to generate 6502 code, and I gave up when I got sick of
all the high-byte/low-byte garbage-- the compiler would have turned out
twice as big and twice as slow.
   And who wants to run ST programs, anyway? (:-)

 - Joel ({allegra,ihnp4,seismo}!uwvax!uwmacc!oyster)

P.S. I'd like to change my "split the group" vote from a no to a yes, just
so the obnoxious amiga/mac/ham-radio cross(and mis)-postings go away.

In article <374@3comvax.UUCP> mykes@3comvax.UUCP (Mike Schwartz) writes:

>By the way, (no offense intended) it seems to me that the people who ae
>so pro ST like to exercise the left half of their brains while the pro
>Amiga people exercise the right half. To the left-half people, monochrome
>text in high resolution is appealing. To the right-half people, high-resolution
>color, speech, audio, etc. is appealing. To each his own, but as a right
>brainer, I have a monochrome hi-res (640x400) AT&T PC to satisfy my left
>brain, and an Amiga, Commodore 64, and Atari 800 to satisfy my right.

What????? Who says that the st doesn't have hi-res color?? 640 x 200 in hi res with 512 colors isn't?? The IBM does 320 by 200 with 16 colors.
No speech synthesis??? If an Atari 8bit machine and a commodore 64 machine can do speech synthesis through software with a program called SAM, then who is to say the ST won't be able to do it yet. Besides, I think the speech synthesis on the Amiga sounds alot like that produced by SAM (maybe that company created the software for the amiga's sound synth.).
No audio??? Well, granted it only has 3 voices but if you listen to the music produced by the programs Barraticus and Sundog, you'll realize that the quality is fantastic!! Besides, a professional musician wouldn't, I assume, hook his computer to a microphone to play music!!! They'd use a midi interface (built in on the ST and extra cost on the Amiga).

Now..... I have been in all the computer stores in the Buffalo and Erie county computer stores. I have seen a total of 5 different Amiga programs: 4 games by Electronic Arts, and one graphics program. I have seen no less than 90 commercial ST programs on dealers shelves. For the benefit of ST users, I would like to list them here:

Business: VIP Professional, How to write Business Letters, How to write your own Will, Letter Processor, Typesetter ST, Haba Write, Hippo Simple, Chat, ST-Talk, Antic Color Sprite Editor, Degas (graphics arts), Final Word, a midi program (can't remember the name), Hippo Rolodex, Hippo Checkbook Balancer.

Languages: Hippo C, Modula-2, OSS Personal Pascal, Michtron Forth, Dragon Group Forth.

Operating Systems: TOS (GEM), OS-9 68K, BOS, Micro C shell.

Utilities: Michtron Ramdisk, Michtron Printer Spooler, Michtron BBS, Hippo Ramdisk, Hippo Spooler, Micronomist Disk Analyser.

Entertainment: Mom and Me, Murray and Me, Barraticus, Sundog, Infocom line of Interactive fiction, Kings Quest II, Ultima II, Hippo Jokes and Quotes, Crimson Manor, Perry Mason, Mudpies, Hex, Alien Adventure Hacker, Borrowed Time, Hippo Almanac.

Educational: Typing Tutor, Winnie The Pooh in the 100 acre wood, Mathbusters - Homework Helper, Word Forth (crosswords), Maps and Legends (Antic), Cartographer.
(not to mention that Spinnaker plans on releasing its complete line of educational software)

Public Domain Software:

Printer Spooler, Ramdisk, Assembler, pop up calculator, Megaroids, Dragon Forth Demo Disk (working subset of Forth), Degas Graphics Slide show, Neo Chrome slide show, Breakout in TOS, etc... etc...

These are actual programs that I have seen on the shelf!! Most of them I have already seen demonstrated. The software programs are in the same price range as most 8 bit computer software --> $25 to $40. I have seen a list of close to 400 programs that are supposed to be available, but I cannot vouch as to their availability. I'll post a list of new software every few weeks or so to keep people up to date.

Last nite I attended our local Atari user group meeting, took some notes, and posted them to our local notes file within the Digital network. I then wondered if any of you out there in USENET land would also have an interest. Since there was lots of good Atari info I hadn't seen before, I am posting a copy of the message below.

While sitting in on last nite's ABUG meeting I took a few notes, and thought I'd share them with those of you who are interested but couldn't made the meeting for one reason or another.

There were two ST's and one 800 set up running demos at the meeting. One of the St's was a monochrome. 8-bit and 16-bit library updates were discussed and I gave a review of the ST info I'd gathered in these notes files, the USENET network, and the news at the recent BCS ST meeting, as well as the info I gathered from my call to Atari (which is now in this notes file). I also gathered a few new ST programs from Dave Davis.

The subject of 1 meg upgrades for the ST came up. Both Harry Steel (the former ABUG librarian) and John Hajinlian do them, or know someone who will do them, at a cost ranging from $125 to $150 (also, see below).

But by far the most interesting event was the talk by Thom of Compuclub of Natick, Ma. I would judge his talk easily the most enjoyable and informative of any ABUG or BCS ST meeting I've attended so far. Even when I left at 10:30 there still was a small group clustered around him asking questions. And he gave a LONG presentation.

I'll try to give a brief (very, considering the length of his talk) summary of what Thom had to say. Those of you who were there, feel free to add.

A very brief intro to the game "Alternate Realities" was shown, and the claim was made that this was possibly the best graphic adventure yet for the Atari! However, early versions were sold with a bad disk that prematurely caused you to die of a "bad disease".

Atariwriter plus is out for $37, and PLATO is out for $20.

The rest pertains to the ST:

Philon Basic, 250 p. manual, is out for $75, but no graphics or GEM interface

Henry's Basic, an interpreter, is 6 x faster than ST Basic, but has no graphics or GEM interface either.

Atari is working on a hardware emulator for the IBM PC, using an 8088 CPU in a box that plugs into the hard disk slot, to cost less than $300. It now runs 80% the speed of the PC, but is expected to improve.

The CPM emulator is selling for $38.

The 1040 will be shipping Thursday, for $200 more than the 520ST.

Compuclub sells the 1 meg upgrade for $130 installed. This may be the best deal going since they are an Atari dealer, can also install the TOS ROMs and also the battery powered clock option (these things are a few dollars extra, however)

The TOS ROMs are probably 2-3 weeks away from general availability.

Unix for the ST looks to be 60-75 days away.

The OS9 operating system will sell for less than $100.

A DBASE II close is coming out for $75 & will be called H&D Base

If your ST kept failing when new, it was due to a faulty power pak. The newer power paks do not have this problem. If you haven't seen it on your ST, don't worry.

520STs with the new ROMs in them are supposed to be coming in 8 days.

An ST cart having a clock in it is coming out by Softlogic in about 2-3 weeks. Thom just saw a beta test version of it. It'll cost $50.

A very brief demo of the "Borrowed Time" game was given - it appeared to have nice (semi-static) graphics.

Intuit, a 1-2-3 clone which now runs on an IBM PC, is 2 months away.

The Atari hard disk (one of the two?) is 20 meg in size and will sell for $799. The Bit Bucket, in Newton, Ma, has one now, and loves it. It has a built-in coprocessor, is a 5 1/2" drive, and you can hang up to 8 of em on an ST.

Atari will have an expansion port that will hang on the hard disk port, and will sell for $75.

A beta test of GEM Draw was demoed - it looked pretty good.

Lechmere Sales is selling the ST now, and Sears is considering it now.

Compuclub sells 6' disk drive cables for $20, so you can buy one, cut it up and use it for experiments.

Thom says that the few people he has seen who have used Modula II for the ST think it's spectacular.

The language APL is less than 30 days away (its by Phylon). Phylon and Atari also have COBOL coming.

A brief discussion of Atari and Amiga ensued, and Thom said Atari really didn't see itself competing with Amiga, since they were after different markets.

Compuclub sells the 520ST for $850, $700 for the mono version. The 1040ST will go for $1150, 950 for the mono version. LOGO, BASIC, and 1stWord will be the software shipped with them.

Thom said to watch out if you are trying to save money on an ST system, since Atari is coming out with a 14" color monitor for the ST which is about $100 cheaper but has less resolution than the current color monitor. Be aware of which monitor you are getting when you buy a packaged system.

Thats the end of my notes. If you would like to confirm any of this (or argue about its validity), give Thom a call at Compuclub, at (617)879-5232. But call after about 11:30 am EST since I think they start their business day about then. I have no connection with Compuclub except that I did buy my ST there about 4 months ago.

I've seen the news from germany that the emulator does indeed
seem to be ok to use for free, now...
We lost our feed for about a week, and it seems clear
from the traffic that I've seen that I've missed something.
Question: has anyone figured out how to get stuff TO the
disk? A blank TOS disk seems to work - you can use "SAVE 10 TEST.TMP"
to save a file - but how do I get anything there to begin with?
Sorry about posting to the net.

By the way, I'm still willing to provide the sources and compiled
atari versions of my screen editor TVX which I posted a couple
of weeks ago to anyone interested.

I just heard that motorola introduced a graphics processor with
a 68000 core. Anyone know any more information? Any idea whether
existing 68000 systems such as the mac or atari 520ST can be
retrofitted with this chip. Thanks for any info.

Summary: PD 'Action' compiler sources (8 bit)

I have a collection of PD programs in Action, primarily from 3 sources:

-The bbs that Clint Parker (author of Action) maintained until last Fall.
-The bbs that OSS (marketer of Action et al) sometimes maintains.
-A few things that I adapted or wrote.

There are various utilities, including a good UNIX terminal with termcap,
examples of how to make the Atari do various things with graphics etc.,
nothing significant in complete games.
I am quite willing to upload all of this, if it isn't much hassle to
distribute or post or archive or whatever. I hesitate to post it
because it would make a lot of traffic on the net and would expire soon
anyway. I have no idea whether some of it is the archives, because I don't
know how to access that or add to it. (Where does one learn that?)
One program, Palevich's VT52 emulator + kermit, was once mentioned as if
it was posted or archived, for example.

How Public Domain can programs ever be that are translations of
copyrighted magazine programs, or of UNIX C utilities? Not much, I
fear.

There is fairly nice ST ONLY magazine called ST Applications. It has
been around since September or so last year. In addition to features
the regular departments are:
     - You Can do it - all about the 68K chip and machine lang.
     - MIDI Beat
     - Let's C
     - A Step FORTH
     - Purposeful PASCAL
     - Ask ED
     - BASIC know-how
Each month they have Reviews of Software, and a ST BBS review. Each
month also has a pretty entertaining rumors section. The current
issue is 70 Pages.

     Subscription: $25/6 or $40/12 issues printed
               $60/6 or $100/12 issues+disk
          ST Applications
          10760 Hwy 116
          P.O. Box 968
          Forestville, CA 95436 (Check or MO only)

Re: previous inquiry about Atari ST and books on it...

As a new owner of an 800XL, I have recently scoured the bookstore walls for
Atari books. I have consistently found all COMPUTE! books to be excellent,
certainly among the best available on all aspects of the 800XL. Their
magazine staff seems to be outstandingly competent at describing and
~~~~~~~~~~~~~~~~~~

programming not only the Atari products, but also those of Commodore, Apple, TI, and IBM. This suggests to me that they will quickly become expert on the new Atari and Commodore products as well.

I would expect any books they publish on the ST and the Amiga to be well worth buying.

The Bit Bucket on Rte. 16 in Newton is one Atari ST dealer. For those who think Amiga is competitive with the ST, they have that too. The phone number at the Bit Bucket is (617) 964-3080. NOTE: I just read in another message that the Bit Bucket has the 20-Mbyte Hard Disk for the ST!!!! (A demo unit only, I fear!)

Re: where to put the memory...

The 65816 sounds like a very nifty idea to me, but certainly no substitute for buying an ST if you desire one. As an upgrade for the 800XL, it would be desirable to keep everything as compatible as possible. Since Atari has already devised a scheme for banked memory in the 130XE, and CDY and others(?) have successfully and compatibly extended that scheme to at least 262K, it would make sense to keep the current banking scheme. See Mapping The Atari, 1985 edition, Appendix 16, page 238, for a full description of the 130XE memory management scheme. Basically, they put the extra memory into the 65K memory map by replacing the original 16K segment between $4000 and $7FFF (decimal 16384 to 32767). Location $D301 (decimal 54017) controls the bank switching. Two bits there are used to control which of four possibilities occur with regard to whether the CPU or the ANTIC chips stay with standard memory or use the selected 16-K bank of extended memory. If you add more than 131 K but stay with their conventions you can always switch to XL/XE compatibility mode to run "old" software. Note that with this arrangement, both the low memory area and the high ROM area are unaffected. This is why everything still works (can be made to work easily).

Re: why to do the conversion

I concur that the reason for the conversion is to get more addressing flexibility within the 65K memory space. A whole lot of assembly language programs will be easier to write and more compact with the extended instruction set. If the 65816 in fact is truly object-code upward compatible with the 6502, I for one am CERTAINLY going to want to drop one into my 800XL even though I bought it basically as a toy computer and for use in ham radio applications and general electronic fooling around. This will in no way affect my interest in adding an ST to the collection for more serious work.

By the way, does anybody know when this chip will really be available; where; and how much? I would appreciate solid info.

   I'll add my experiences to jhs'. I've just let my year-long subscription to Compute! run out, my Antic subscription is into its 7th month, and my Analog subscription just started (though I have the last 4 issues). I agree with most of the comments, but will add my own.

>Antic and Analog are entirely devoted to Atari products and have
>significant sections devoted to the ST. COMPUTE! is fairly evenhanded amongst
>the small personal computers including IBM, Apple, Commodore and Atari, but
>still has devoted significant efforts to the ST (as well as the Amiga).
>COMPUTE! has in the past provided much excellent information in book form, and
>I suspect that they will soon carry the tradition forward to the ST products.
>I have been much impressed with their virtuosity on the 8-bit Ataris, so I
>suspect that they will continue to be one of the better sources.

   Compute! does seem to have their act together. However, due to the fact that they cover several flavors of machines, the Atari-specific material is necessarily low. They come out periodically with collections of articles and programs for each machine- there are currently three for the Atari. Support the magazine if you like; I'll scan each issue on the newsstands, and wait for the compendiums. After all, I only have so much money to spend on magazine subscriptions.

>Antic seems to be more game-oriented than the others. Depending on your
>interests and applications, this may be good or bad.
>
>Analog seems to have the most complete selection of software and accessories

>specifically for Atari products in its advertising. It seems to be more
>"technical" than Antic.
>
   The above two paragraphs are almost word-for-word what I told the Micro
Center people here when my opinion was solicited. However, don't let that
steer you away from Antic. They still have many non-game applications,
and best of all, handle the old APX software. Lots of useful software
that you see mentioned on USENET is available through them. Some of the
titles that have been popping up recently are Deep Blue C, Chameleon
terminal emulator, and Dandy (see the "Gauntlet" postings in
net.games.video). Also, Antic has a UK edition (at least that's the im-
pression I got); I'm not sure about the others.

Motorola was coming out with a graphics processor as part of the M68000 family, but it was cancelled recently. The chip was being designed at the Motorola facility in Austin, Texas by someone I know very well. I will not go into the reasons for the cancellation, since I don't want to get in trouble with Motorola, but according to this person I know, the reasons were more political than practical.

Disclaimer: I don't work for Motorola. The opinions expressed here are mine. Motorola may release some "official" reason for the cancellation which may or may not agree with what my contact told me.

BTW, from what I was told, the chip was pretty sharp. Resolution on the order of 1K by 1K, 8(?) bits of color (256 colors overall) from a virtually unlimited palette, bit blitting, etc. I can't remember what else. It was a really hot ticket.

Don Nash

Quite a while ago, when atari was demonstrating the pre-production ST's
they showed a 'Breakout' desk accessory... Does anyone on the net have
a copy ? Is it in the public domain ? If so, could someone post it,
or if possible, the source.

Thanks in advance, etc.

Every now and then, such as when exiting from an application back to the
desktop, the cursor wanders by itself in one direction. As soon as you
move the mouse, you regain control. Otherwise, the cursor just bashes into
the side of the screen. Has anyone else experienced this, or am I just
loosing my grip on reality ?

P.S. I am using a fairly old version of TOS.

Thanks.

Some disappointing news regarding the possibility of the 65816 as a possible upgrade for the 8 bit line :

I seem to recall an very detailed article regarding the new chip in a special issue of BYTE magazine on the topic of "New Chips" (within the last year). Some months later someone wrote in to "Ask Steve Ciarcia" in BYTE enquiring as to whether the 65816 could be easily installed in place of a 6502. His answer was no...

I don't have either of those issues anymore however, if anyone out there does maybe they can fill us in on the detail.

There is an interesting article about Atari in the Jan 27th issue
of Electronic Engineering Times. The author was very positive
about Atari and the directon Jack Tramiel has been taking them.
Some of the points were:

     Atari is continuing to sell about 15,000 units a month

     Warner has written off $240 million in notes from Atari

     Atari's finances are almost at a break even lpoint

Developers are selling more software than they expected to
at this time. (DEGAS has sold more than 10,000 copies)

Also the article was positive about the two tier marketing aproach
for the ST line (520's in mass market, and 1024's in the computer
stores).(I still think that the mass market move was good, but
the JS&A approach is going to give the machines a bad name).
By the way, I purchased DEGAS last week and I am really happy
with it. Hopefully we will be seeing more good news about
Atari and the ST in the future.

[NETINFO:KERMIT-TAC-INFO.TXT] [updated 8/13/85]

QUICK GUIDE TO USING KERMIT THROUGH A TAC

ASCII FILES

1. What kind of file are you transferring? If a text file, it should be straight ASCII with no control characters (Wordstar files should be run through a conversion program).

2. Does your PC Kermit allow the packet size to be changed? (MS DOS Kermit does; check your manual).

   If YES,
   then set the send or recieve packet size to 60
   on both the PC Kermit and the Host Kermit.

   If NO,
   then enable flow control (XON/XOFF) on the PC Kermit.
   Enable flow control on the TAC by typing:

   ```
   @D C A
   @F I S
   @F O S
   ```

3. Change the TAC intercept character from "@" to "^F".
   To do this, type this command to the TAC:

   ```
   @I 6
   ```

4. Do the file transfer.

BINARY FILES

1. Your host must be able to support binary mode. Put the TAC in binary
   mode by typing:

        @B O S
        @B I S

2. Transmit the file.

[CU20B, DDN-TAC.HLP]

Date: Mon, 25 Feb 85 15:49:04 EST
From: Edward Haines <haines@BBNCCI.ARPA>
Subject: Kermit and TACs
To: Info-Kermit @ cu20b

Using Kermit with an InterNet Terminal Access Controller (TAC).

There are some conditions that must be met to successfully use Kermit on a personal computer through a TAC.

Flow Control

The buffer size for a terminal port on a TAC is typically about 64 bytes. (The size is a configuration parameter.) Since the default packet size in Kermit is about 96 bytes it is quite likely that buffer overflow will occur.

Some possible solutions:

1. Enable flow control in Kermit on the PC and on the TAC. Many PC versions of Kermit implement XON/XOFF flow control. In particular, the new MS-DOS version does for the IBM PC. To enable flow control on the TAC issue the TAC commands

  @Flow Input Start
  @Flow Output Start

These are usually abbreviated @f i s and @f o s. Note that flow control is not compatible with binary mode (except see note below).

2. Make the packet size on the PC Kermit small enough to not overflow the TAC buffer, e.g. 60 bytes. I had patched the old MS-DOS Kermit to do this. On the new MS-DOS Kermit, there is a command to set the packet size.

3. Increase the buffer size in the TAC. This is not usually practical and won't be considered further.

TAC Intercept Character.

The default TAC intercept character is the AT-sign. The AT-sign is also required by the Kermit Protocol.

Solutions

1. Have the PC Kermit automatically double AT-signs on output. This is probably the best solution in general. This feature is available on some PC implementations of Kermit. It is not yet available on the MS-DOS version. [Ed. - It's available in CP/M-80 Kermit 4.0x.]

2. Change the TAC Intercept character with the command

```
@Intercept <decimal ASCII value>
```

I generally use @I 6 which sets the intercept character to Ctrl-F.

3. Put the TAC into Binary mode. This has the side effect of disabling the Intercept character. It also will allow you to transfer binary files without special encoding. The TAC can be put into Binary mode with the commands

```
@Binary Input Start
@Binary Output Start
```

Some host systems allow you to engage the binary mode from the host. [Ed. - DEC-20 Kermit has a command for this.]

There are several problems with binary mode:
- Some host systems don't support it.
- You lose the ability to control the TAC from the PC.
- You lose the ability to do XON/XOFF flow control.

Binary Files

It is sometimes desireable to be able to transmit an 8-bit binary file between a host and a PC. The TAC (which implements the DDN Telnet Protocol) normally provides just a 7-bit ASCII path.

Solutions

1. Enable binary mode (if possible) as described above.

2. Enable 8th bit prefixing (if available) in both Kermits. (This is usually done by enabling parity.)

Notes

1. You will probably get the best throughput for ASCII files by keeping the packet size as large as possible and using flow control.

2. There is not much advantage in increasing the baud rate between the PC

and the TAC beyond 1200 baud because of the realatively long turnaround time for the acknowledgement packet.

3. You may have problems when going through satellite hops or multiple gateways due to the occasional very long delays. This may result in Kermit giving up. I have also seen Kermit get into a sort of resonant mode where it sends each packet twice but is otherwise succesful. [Ed. - The resonating packets usually happen when one of the Kermit programs is not capable of flushing its input buffer. See the BYTE article for an explanation of this phenomenon. Long delays can be circumvented to some extent by increasing the timeout interval; many Kermits have commands to allow this.]

4. Only the first letter of a TAC command is required.

5. It is possible to set binary mode in only one direction. For example you can set Inbound binary and retain input flow control (XON/XOFF flow is in the opposite direction). You probably don't need outbound (input to the PC) flow control when using the Kermit protocol.

I need information on public domain word-processing programs for the 8-bit line. In particular I'm looking for something that will work with 1027 printer. I would also appreciate comments regarding experience with the 1027 (e.g. how reliable is it ?).

I will summarize and post info on the word-processing software.

The default TAC intercept character is the AT-sign. The AT-sign is also required by the Kermit Protocol.

Solutions

1. Have the PC Kermit automatically double AT-signs on output. This is probably the best solution in general. This feature is available on some PC implementations of Kermit. It is not yet available on the MS-DOS version. [Ed. - It's available in CP/M-80 Kermit 4.0x.]

2. Change the TAC Intercept character with the command

```
  @Intercept <decimal ASCII value>
```

I generally use @I 6 which sets the intercept character to Ctrl-F.

3. Put the TAC into Binary mode. This has the side effect of disabling the Intercept character. It also will allow you to transfer binary files without special encoding. The TAC can be put into Binary mode with the commands

```
  @Binary Input Start
  @Binary Output Start
```

Some host systems allow you to engage the binary mode from the host. [Ed. - DEC-20 Kermit has a command for this.]

There are several problems with binary mode:
   Some host systems don't support it.
   You lose the ability to control the TAC from the PC.
   You lose the ability to do XON/XOFF flow control.

Binary Files

It is sometimes desireable to be able to transmit an 8-bit binary file between a host and a PC. The TAC (which implements the DDN Telnet

Protocol) normally provides just a 7-bit ASCII path.

Solutions

1. Enable binary mode (if possible) as described above.

2. Enable 8th bit prefixing (if available) in both Kermits. (This is usually done by enabling parity.)

Notes

1. You will probably get the best throughput for ASCII files by keeping the packet size as large as possible and using flow control.

2. There is not much advantage in increasing the baud rate between the PC and the TAC beyond 1200 baud because of the realatively long turnaround time for the acknowledgement packet.

3. You may have problems when going through satellite hops or multiple gateways due to the occasional very long delays. This may result in Kermit giving up. I have also seen Kermit get into a sort of resonant mode where it sends each packet twice but is otherwise succesful. [Ed. - The resonating packets usually happen when one of the Kermit programs is not capable of flushing its input buffer. See the BYTE article for an explanation of this phenomenon. Long delays can be circumvented to some extent by increasing the timeout interval; many Kermits have commands to allow this.]

4. Only the first letter of a TAC command is required.

5. It is possible to set binary mode in only one direction. For example you can set Inbound binary and retain input flow control (XON/XOFF flow is in the opposite direction). You probably don't need outbound (input to the PC) flow control when using the Kermit protocol.

My 520ST is having trouble writing to floppies. For example, the TOS formatter gets to the working box, but then the screen goes white and the system crashes. The system also crashes when creating and deleting files, or when saving NEOChrome pictures. However, Megaroids does successfully write the high score file.

Write-protected floppies are recognized; with protection removed, the system crashes on retry. After rebooting, I find the floppies are not formatted. Files do get created and deleted, although the files are always empty.

I have the standard issue 520ST system with color monitor. The hardware seems to be working ok; I can boot the system, list files, and run programs.

Does anybody have any ideas about this problem and its fix? My main mail address is clayton%thumper@mouton.arpa

Thanks.

About three weeks ago a friend of mine at Epyx here in Sunnyvale informed me of the possibility of Commodore filing for bankruptcy. Since he did not tell me where he heard this from, I kept it off the net.

However, this morning (1-31-86) the stock market reporter on an ABC radio affiliate in San Francisco, KGO, announced that Commodore's creditors have told the company that today is the day that they have to pay up. This is after one previous extension of a payment deadline.

My friend was right.

Will Commodore survive?

One final note, during the past few weeks Commodore stock has fallen nearly 40% and is now selling(!?!) for less than $7 a share.

A couple of years ago while finishing my MS from Boston University, I wrote
a simple relational database manager for the Atari 800/etc. called RDBMS/AT.
Due to the 48K memory limitation and slow processor I wasn't able to include
a lot of the functionality that one would expect from a DBMS. However, the
package, which consists of subroutines that one includes with his or her
application code, is very useful.

I was thinking the other day that with the advent of the ST, we finally have
a machine that can do some powerful database functions. So, I'm proposing
in this mail that interested persons combine forces to produce a powerful
public domain database package for the ST. Once it is available, people could
use it as the basis for their application programs. Because it is in the
public domain, it would be free for all to use and could evolve with the
growth of database technology. I'm not thinking of a finished package like
DBASE III but of subroutines that provide database primitives and thus
could form the nucleus of finished programs. If enough people are involved,
a common design could be implemented in several languages.

So if you are interested, send me mail. I don't have nor plan to get a
ST (alas my budget has higher priority needs), but I am willing to collect the
names of interested "hackers" and help get the idea started. Also, I would
like to be involved with the design (I'm not a database guru but would
contribute what I can and would learn from all involved...)

Allen Leigh, DEC
...decvax!decwrl!dec-rhea!dec-cache!leigh

p.s. if any of you 8-bitters would like to look at RDBMS/AT as a tool for your
software development, send me mail. I have a formal release from DEC and
its ok to give it out to anyone.

A very good home control application of your machine might be an enviroment
control unit. this would monitor the temp of your house (this could be done
with thermal resistors). the program could turn down the heating at night,
up before you wake in the morning, down while you are at work... etc.
on the same idea, it could also handle cooling in the summer... turning on
fans or air contidtioner ... whatever
these are things that make a computer finally seem like so much more than
a toy...

I would like to add my experience to these rumors. Having an early 520ST
(rev A) I was able to upgrade to 1Meg. Now the bad news: The now avai-
lable ROM version of TOS will ignore this upgrade. It will still work if
the additional DRAMs are in but without using them. Furthermore if you
change the appropriate system variables to update top of memory and 'MMU"
configuration byte the system will NOT work after a reset. One has to turn
it off and on again. I haven't found the routines yet who make it appearently

impossible to utilize a selfupgraded 520ST (any hints?)

Some remarks about the ROM version:
The ROM version seems to be more stable when recovering from a system crash. It boots up in ~less than 10 seconds (still reads the *.INF and *.ACC files from disk). The 'MUSHROOMS' were replaced be the pictore of little bombs (they DON'T explode).

I have been following the discussion on upgrading the 800XL with the 65816 processor.The main problem that I see is that ATARI didn't use a standard 6502 in the 800XL it's a special version made for them that has some of the pinouts changed and new signals added to the chip.This chip is code named "SALLY" and in the 800XL repair manual is says "6502c (modified)"pg 1-5.In particular the r/w pin is 36 and a new input is"HALT" at pin 35.All of the 65xx family manuals that I have, don't contain a chip like this.

We need help!!!!!!!!!!

We just got our Hard-Disk from Atari (Beta-Test). Unfortunately there
was not a single sheet of paper, which tells how to get it up and running.
If the power is switched on, the disk does something (self-test of the
controller???) but what. Reseting the 520ST does not boot the hard disk
(The Hitchhikers Guide (26.Aug.85) says that this is ok). But booting
from floopy and then creating a drive "C" for the hard disk doesn't
work either. So any hints are welcome. Please send your mail to

Roger Swan asked about home controllers and software clocks, etc. There
is a program in Analog that puts a clock in the border region of your
screen that stays there and lets you use your Atari as usual. I don't
recall which issue, but I >think< it's from last summer. If I remember
to look at home (don't count on it), I'll post the reference next week.

I would also be very interested in source code or references to info about
programs for home control. I believe there is a large untapped market out
there for such applications of 8-bit machines.

I just picked up Modula-2 by TDI and I'm very excited about
it from my first impression! I got it at Instant Software
in the Nashua Mall here in New Hampshire for $69.95.

It's about time somebody (namely Dr. Niklaus Wirth) put
together a program development language that makes good
sense! This language is what I've only dreamed about
in the past. It's structured programming at it's finest.

Unfortunately for me, I don't have the development package
from Atari, and therfore will be fumbling for a while until
I can understand the AES and VDI interfaces.

Is anyone aware of documentation that exists or may come
out soon on the AES and VDI interfaces?

I highly recommend Modula-2 for anyone who really wants fast
executable code and wants to harness the power of the 68000.

It's a GEM of a product, and well WIRTH the price!

In article <2048@watdcsu.UUCP> dmcanzi@watdcsu.UUCP (David Canzi) writes:
>To refresh a 640 by 400 bit screen 70 times per second from memory 16
>bits wide requires reading memory 1.12 million times per second.
>It takes 4 clock cycles (minimum) for the processor to read a word from
>memory.
>With an 8 megahertz clock, the screen
>must be slowing down the processor by at least a factor of 2.

Three possibilities here:

1: The hi-res mode is really 70 hz interlaced.
     At the 70HZ rate you could not tell visually, you would have to use a
     high speed camera and a short persistance monitor to even tell.
     Some very high resolution video and CAD/CAM systems have used this
     successfully to attain very high resolution when bus bandwiths
     are to slow for say 4096x4096 by 4 colors.

2: The MMU chip may include a syncronous address multiplexor (SAM) circuit
     similar to the 6883 used in the TRS-80 color computer. This circuit
     allows a second device to use the memory during the period that the
     CPU is "announcing addresses".   The MMU provides VMA
     to allow the CPU to continue the set up, when everything is ready,
     all of the CPU signals get sent to the memory at the same time,
     then DTAK is dropped. The effect is to cause the two different
     processors to access memory 180 degrees out of phase with each
     other and latch/tri-state the various signals. TI does this
     in their dual-ported video RAMS for systems where a SAM is not
     practical.

3: Other assistance, such as FIFO's in the video chip
     (8275 style), or in the MMU chip can compensate for the irregular
     timing of the CPU fetches. This would also allow video or DMA
     circuitry additional access during CPU execution cycles, ROM
     access cycles, and other "RAM-Idle States".

There is a good possibility that all of the above were incorporated. As evedenced by the requirement for fast (120ns) rams, 'raster crawl' visible under a magnifying glass, and the fact that the video doesn't "Glitch Out" during things like timer loops, which demand heavy buss acess. I suppose we'll have to wait for Atari to divulge the finer points of these not too well documented chips. Or wait for a good hacker to try "poke-blasting" the MMU/Configuration addresses. 512 of these are indicated but not well described in "Presenting the Atari ST".

Hardware is my hobby, so a good engineer may have a better answer for you than this.

I am having a problem. The following program SHOULD re-instate an OSS "supercartridge" after being 'removed' by a similar program (the only differences are between the SEI and the CLI). When I enter Action! from OS/A+ after turning the cart off & on w/ these programs, I get MUCH garbage on screen (pretty lights, different modes on each line!) & have to re-boot.

I am not too good w/ assembly language & a borrowed entirely some code from a similar program for turning the XL basics on & off (published as DATA statements in Compute! & hand dis-assembled.

Could someone tell me what I'm doing wrong here??

Atari has made no special effort to prevent someone from upgrading
a 520-ST to 1Mbyte. I think that some early memory controllers had
some problems with drive capability for a second bank of RAM chips,
but none of those controllers made it into production machines.

I have heard horror stories about companies doing 520-ST upgrades to
1Mbyte (one developer said his machine came back with only 2 of the
6 OS PROMs, and that the machine had been busted in other, more
subtle ways.) BE CAREFUL! Go to someone reputable; make sure that
you know that they know what they are doing ....

Atari should be on usenet presently, within two weeks, tops. When
we are finally and solidly up, I'll let you know.

Summary: are they for real?

Has anyone purchased either of the Hippo sound or video digitizers advertised
in the March '86 Antic? They *sound* good. For those of you who haven't seen
the ad (and in the hope of luring someone into buying it and getting a review),
I will repeat the ad below...

HIPPO ST SOUND DIGITIZER
     Digitally sample, modify, and play back high-quality sounds. Experi-
     ment with adjustible real-time echos, phase shifts, voice synthesis
     and recognition, and fourier analysis. Adjustible sample and playback
     rates. Software includes many fun demonstrations including a real-
     time graphic oscilloscope. Useful for analog lab measurement and
     control too. Includes software (executable and source), hardware,
     microphone, power supply, and instructions. $139.95
     THE SPECS: 8 bit A/D and D/A // 2.5 microsec flash A/D conversion rate
     allows sampling up to 400,000 samples per second // 1 volt peak to
     peak signal and source // Hardware plugs into printer port for high
     speed data transfer rate.

HIPPOVISION VIDEO DIGITIZER
     Digitize from any standard composite video source (e.g. TV camera, VCR,
     TV tuner, etc...). Frame grabber "snaps" color picture in a single
     video frame. Creates Neo files. Perfect for game-designers and art-
     ists. Send video pictures over the phone (requires a modem)! Includes
     hardware and software. Contact us for high-quality color printers and
     ST color printer software drivers too. Call for price.

THE SPECS: 256x256x9 bit resolution (3 bits per color) // Standard NTSC 1 volt peak-to-peak composite sync signal // Software color "voting" system picks optimum 16-color ST palette according to image // Hardware plugs into printer port for high speed data transfer rate.

Yeah, advertising makes me sick too. But if either of these devices deliver what they claim, they could really enhance an ST. Consider working on a video image in Neo that started as a single frame grabbed from the movie BLADERUNNER! The sound digitzer can be used to analyze sound from actual instruments and thereby simplify manyfold the task of creating the "patches" for those instruments for digital synthesizers. However, I'm as aware as the next guy about HIPPO's track record for producing problem-free products. This is why I'm hoping that someone to whom $139+ doesn't represent such a big investment will take the plunge and enlighten us all.

BTW, if you *do* want one...

HIPPOPOTAMUS
985 University Ave., Suite #12
Los Gatos, CA 95030
(408)-395-3190 (that could be 5190, my copy is bad)

Don't flame me, I have flash paper underwear. Thanks.

The kludgy way: Install a printer that has the command to set double
spacing in the initialization string.

> the program operates in a
> "document" or strictly ascii mode. the annoying thing is if you save
> some text as ascii you can't convert it back into a document and use the

Well you can - sort of:
Simply :-) turn all spaces in the ascii file into what they call "variable
spaces". I have a little c-program for doing that. But it's on a disk I
don't have here at the moment.

The San Jose Mercury News reported this morning that creditors have given
Commodore another extension while they negotiate on re-arranging the loans
that are in default. If it doesn't work out, Commodore will probably have to
file chapter 11 for protection.

> 	Will Commodore survive?

Hard to say. Even if this latest extension fails, Commodore can operate under Chapter 11 until it gets itself going again. Being bought by a company looking for entrance into the personal computer market is another option. I think the chance of it just disappearing into the sunset some afternoon is quite small.

> One final note, during the past few weeks Commodore stock has
> fallen nearly 40% and is now selling(!?!) for less than $7 a share.

It might well be a good buy if you're looking for a speculative stock. If they can pull off a turnaround, the stock will take off. If they file chapter 11, it'll probably drop to around $1 or so. I wouldn't write them off at all, and if everyone else is selling, contrarian philosophy says to buy. It'd be a high risk (don't bet your retirement on it) but could also pay off quite well. Look at chrysler stock.

There have been too many "please delete" messages sent to this list, from ninnies, twits, and cretins who refuse to read or comprehend simple instructions. Today, there were over a dozen in my mail file.

To reiterate: Requests to be ADDED TO or DELETED FROM the INFO-ATARI list should be sent to:
INFO-ATARI-REQUEST@SU-SCORE.ARPA

Note the "-REQUEST" in the address, kids. The same convention is used in hundreds of other mailing lists.

     If the flow of please delete messages does not stop, I will set in motion a program that will repeatedly bombard the culprit's mailboxes with megabytes of junk mail from all directions, with no obviously discernable means of filtering out the junk short of deleting all your mail. If you think your UUCP or BITNET charges are high now, just wait until I get through with you.

     Moderator, I suggest that you decline to add any new people to the INFO-ATARI list until they send you a message (at INFO-ATARI-REQUEST) containing the following: "Please add me to the INFO-ATARI list. I understand that any change in my membership, including address changes or removal from the list, is to be sent to INFO-ATARI-REQUEST and not to INFO-ATARI."

> It's a GEM of a product, and well WIRTH the price!

I agree with the above article, it is a GEM of a product and well
WIRTH the price etc. However I have the following concerns:

1) The user interface of the compiler SUCKS (please excuse my french -
or is it american -:). Why? Firstly you cannot call up the compiler
from a command line, you have to use the desk top (this is probably
due to gem and not the compiler, but they could have provided two fron
ends). Secondly, your default drive has to be the one containing the
compiler which has some overlay files. In addition all the .SYM files
required by the program have to be on the default disk, you cannot
specify a path for them. You can run the compiler, and it will let you
answer dialogues so that it finds them somewhere else, but it takes
all day to answer the dialog and compile. If your source file is not
there in the default directory, you have to do a lot of work just to
specify the file name to the file dialog (again a problem with gem ,
but the compiler fron end could prompt for a simple file name, sort
of like ttp). Third, compiler options have to be given as comments in
the source code, which means that if you want to change some options
you have to go re-edit your program (the options provided are pretty
useless in any case for majority of the programs). It all boils down
to how they have used the Gem interface. The interface is getting in
the way of using the otherwise excellent product. A .TTP kind of
interface would have been mich nicer for the way they have used it. It
would have been much nicer, if they would have used the gem interface
in the following manner - the files menu would let you specify which
file(s) you want to compile, giving you a dialog to enter the file
names. The file menu has a selection for compile, quit etc, which
allows you the flexibility to compile another file. The option menu
lets you select compiler options and so on. This would of course mean
a lot of shuffling between the mouse and keyboard, so i would prefer
just a simple command line interface, which can be also invoked from
the desktop in a .TTP fashion if you so prefer.

2) Errors: The compiler generates an error file, which contains a
bunch of numbers, which only the editor supplied can understand. This
is fine if you want to use their editor (that lets you go to the next

error), but what if you do not want to use their editor? Why could it not generate a human readable error file too (or may be a compiler option). ?

3) Editor: really slow, very simple minded, has lots of useless menu selections (like under the move menu, it has a selections for line up/down. There are alternate key binding for these functions, so it is not too bad, but this spce could be used much for effectively to privide functions that make sence to have in a menu. It looks like they put up menus just for the sake of having them, and did not consider their utility at all).

4) Linker: The biggest short coming in the whole system is that the compiler produces its own format (.LNK) object files. The linker will only understand .LNK files. This means that implementation modules HAVE to be written in modula. To my mind this is totally RIDICULAS (sp?), modula is not the ideal language for all the things you want to do at the implementation level, though it is great for specifying the interface and dealing with say the object at the higher levels. Again like the compiler it is really painful, when your .LNK file is not in the current directory to specify another one.

5) Library: Xbios and Bios interfaces are missing. There are no routines for LONGINT LONGCARD i/o.

Note that i am mainly complaining about the interface, and not the compiler itself. How do others feel about the interface. The only serious complaint about the compiler is not being able to write implementation modules in other languages, which kind of ailienates modula from rest of the languages and useful libraries in the system.

As far as I am concerned PASCAL is DEAD (finally, good riddance..)

Product: Regent Word 1
Developer: Regent Software, 7131 Owensmouth, Suite 45, Canoga Park, CA 91303
Machine: 520ST
Price: $49.95 (already discounted to $35)

Regent Word 1 is a word processing program which is similar to STwriter or the 8-bit AtariWriter. It retains much of the flavor and features of these older programs (e.g., new line at column 80 when typing, control characters to set parameters, etc.) Word 1 uses the ST as an 80 column terminal -- don't expect fancy windows. It has a preview mode to view a file without printing, but does NOT change font, use bold face, etc. (Phooey!) Current printers supported are Epson and Juki. (There don't appear to be the separate printer drivers as in AtariWriter.)

There are some good features available. All the function keys are used and are bound to some of the more frequently used operations. The help key will bring up the help menu pages (five in all.) Unfortunately, Regent expects users to flip through the help pages in place of good substantial paper documentation. (I am definitely NOT pleased with this situation. If you go to a menu display for help, it will of course disappear when returning to the text display! Printed documentation doesn't have this problem.) There is a word count command which should make students and piecework writers. Special effects are easier to invoke such as bold face, underlining, elongated text, font type, font pitch (Juki), etc. A limited communication feature is included to send and receive files. (Transfers are pure ASCII without any protocol such as XMODEM.)

All in all, Regent Word 1 isn't bad, but is short on flash. About 200K bytes are available at startup (I throw all those ^%$%#@#$ accessories out by the way) so it can handle some pretty big documents. AtariWriter (STWriter) users will feel comfortable with this product, but beware! The key commands are NOT the same. Overall, Regent Word 1 is servicable and should tide us over until "the real thing" comes along for the ST.

Also, a companion spelling checker is available for $49.95 (discounted to $35), but I did not pick it up for testing.

****

I purchased the TDI Modula-2 system and have been using it for about a week. The system comes on two disks. Documentation is adequate, but the manual assumes that the user has a Modula-2 programming manual.

Unlike many of the early programs for the 520ST, this one actually makes use of GEM! I managed to transliterate a nontrivial Pascal program into Modula-2 and got it to run without too many problems.

Since the system is stored on two disks, it is EXTREMELY tedious to use it with a single drive system. I would not recommend getting this program unless:

1. you have a hard disk
2. you have a double-sided drive
3. you have two single-sided drives
4. you have a single drive but can develop your programs elsewhere

It appears that most if not all system routines (GEM, VDI, etc) can be called from Modula-2 programs.

The system is not copy protected. It has usually been my experience that copy-protected programs are usually not worth copying...

Syntax errors are for the most part understandable, and the editor and the compiler are fixed up so that the editor will flag the syntax errors that the compiler discovered.

Although the syntax error messages are plentiful and meaningful, there are only a very small number of runtime errors, which tend not to let you know what went wrong.

The code generated by the compiler is small and fast, and according to the manual, some primitive optimizations are performed (short-circuiting of Boolean expressions).

The linker allows true seperate compilation. One can create libraries that are compiled only once, and then linked into programs using their routines.

It appears that a program written in TDI Modula-2 run on the ST will be
about twice as fast as the corresponding Berzerkely Pascal program running
on a VAX 780...

Of course, your speed will depend on your programming habbits and will be
lower in California.

Keywords: Action compiler, CRC

```
------------------------------------------------------------------------------

    Utility CHECK provides a way to find the length of a file (in bytes,
and in lines for text files), and sorting out different versions of files
(by comparing their CRC's).
    There are two files, CHECK.ACT and CRC.ACT. CRC shows a progression from
a straight Action version, updCRCa, to a machine language version updCRCx
of updCRCa, to a straight Action version that uses a table but is fastest.
    If you compile and write and executable file to be run without recompiling,
consider removing the ; from SET $491... so it will not run on top of
something else. If you have the run-time libraries SYSLIB and SYSIO, remove
the ; from those INCLUDEs to make an executable file that doesn't need the
Action cartridge to run.
    At least with DOS XL, CHECK can be re-run without re-reading it off disk
by just typing 'RUN'. This is the purpose of 'Entry'.
    Other features useful in other programs include:
        fast disk read
        error handling
        fixing up the DOS file name (force upper case, prefix D: if needed)
        locating the buffer
        run-time library does not set device=0; do it yourself in case.

A previous letter stated that compiler generated error files were usable
only by the editor that came with the system.

The format of the error files is:

<line #> <error #>
```

The file is a normal text file. The only problem one might have using
<ignore previous and current line>

One can look up the meanings of the error numbers in the manual (You have
to do this even when using the supplied editor).

Lines: 134

SUMMARY: My upgrade didn't work at first, then did, and I'm not sure what I
fixed. THE INSTURUCTIONS I FOLLOWED NUMBERED THE PINS OF THE MMU BACKWARDS!
The correct numbering is silkscreened in white around the chip. My ST
didn't have any metal shield around the RAMs, and the MMU and Glue chips
were not soldered in, but there was a blue MOD stamp on the box, and there
were some fixes inside. For even moderately-experienced hardware hackers,
this upgrade is fairly easy, and worth it.

I recently upgraded my 520ST into a 520ST+, and I would like to share my
experiences with the net.

When I received my 520ST by UPS, the first thing I noticed was the word MOD
stamped in blue on the outside of the CPU box. I don't know what that
means, but I would guess that it means my ST has been somehow modified. Just
below the word MOD is the sticker with the serial number of the ST, and on
that sticker there's the notation "7 1985" in the same color of blue as the
MOD stamp. If anybody has any clues about this, please let me know.

I ordered 20 Hitachi 150ns 256Kx1 RAMs from Microprocessors Unlimited, and
was, of course, impressed with their performance: all the good things
you've heard about them are true. They took my VISA card number when I
ordered, so they could ship my RAMs right away, and also sent a stamped
return envelope that I could use to send them payment by check. More

companies should do this -- it speeds the process tremendously.

I ordered the chips on Monday, and they arrived Thursday. By Friday morning, I was in the lab on campus with my foil-covered desk, solder-vacuum, and high hopes. Nothing like having the right tools for the job: the vacuum-operated de-solderer made removing the capacitors a breeze.

When I got my mother board out of the casing, I looked it over for any MODs I might find. I saw some obvious hand-work around the MMU chip - on the pins to the left of Pin 1 as I looked at the solder side. There was also some blue solder mask in that area, but I could not see any actual modifications; maybe they just had to resolder that part of the socket. There was also a resistor which had obviously been installed after manufacture: it was in the upper-left quadrant on the component side, near the CPU, and came from one side of a capacitor to ground. Both sides of the capacitor in question were still soldered in place. Finally, I noticed a capacitor which had apparently been replaced, in the middle of the row of capacitors which parallels the mouse and joystick ports. Also, my board was Rev B, and my serial number is A1-102-6982. If anybody knows the meaning of all this, please clue the rest of us in. Thanks.

Piggybacking the RAMs was not rough, but be sure to use a narrow soldering tip: there's not much room between chips, and you have to solder in that channel. Here's a tip: bend the pins of the new RAMs so they come out not-quite-straight down from the package, then seat them on the old ones: you get a decent electrical connection just by the friction, and the solder just has to hold everything together. (Somebody please post something if sliding the pins of the new RAMs over the old ones builds up dangerous static charge.)

The first four chips I soldered on had the wrong pins bent up: I am used to seeing the solder side of ICs, and I counted backwards. I had to de-solder the correct pins and bend and solder the wrong ones... It turned out later that one of the chips involved was bad, so maybe this is when I blew it. The rest I did correctly, and it was really no trouble. Once the pins are pressed against each other, just add enough solder to flow, and it will work fine.

Wiring the busses across the tops of the chips was easy, once I bent the pins almost vertical. If your bus wire is thick enough, you can weave it between the pins to get some tension while you solder. Weave the wire between the pins before soldering any of them, and press down on it so it rests on the chips. Solder the whole Pin 15 (or is it Pin 4?) bus at once, and then cut it in the middle after you're finished: you get fewer loose ends that way.

The instructions I had called for six resistors, and it took me a couple of minutes to find all the places to connect them. What the instructions don't tell you is that the three lower-bank bus control signals come out of the MMU chip together, three traces on the component side of the board. I found that I could slip some spaghetti (insulation from a stripped wire) over the leads of the resistors to get insulated leads, and these worked well for me. In fact, most resistors have long-enough leads to make those three

connections: cut the traces on the top of the board, but solder the resistors on the solder side. You will need low-profile reistors for this: the cylindrical ones are too fat. Use the barbell-shaped ones.

As instructed, I connected the upper-bank bus control pins of the MMU to the busses in the middle, not at one end, for a T shape. This is just as easy, and seems to be a good noise-reducer. I soldered the resistors to the pins from the MMU socket, then soldered wires to the ends of the resistors, and finally brought the wires up through the holes in the PCB to connect to the busses on the component side. Leave a little slack in these wires, because they have to get out of the way of the plastic case which comes up through those holes.

Finally, I was ready to test it. I put some paper down over my foil, connected all the cables (Atari returns us to the Age of Rat's Nest Computers!) and powered up. Glory be, she booted! But my free-ram desk accessory showed the same number as before, not 1/2 meg more! So the top bank hadn't passed the memory test.

I got lucky: I used the memory editor I got from bammi@case, and it demonstrated a one-bit error in the upper bank. Bit Twelve of each word was always zero. Fortunately, the instructions I had told which chip was which bit, so I could pinpoint the problem: it was one of the chips I'd made the counting mistake with.

I removed that chip from the two busses, and de-soldered all its pins. The best way to do this is to get a sturdy hook of some kind (the lead from a resistor bent into a hook is good), catch the pin of the upper pin in the hook, and pull while applying the soldering iron. The pin should come free, and when you've de-soldered them all, the chip will rattle in its position. It was a little tricky to get it out without disturbing the bus wires above it, but I managed it.

Then in with the new chip, and power up, and it booted, and ... GEM still recognized only 1/2 meg. This time, when I got into the memory editor, each reference to the upper 1/2 meg gave a bus fault of some kind (lots of mushroom clouds; more than my list describes). I'm glad this didn't happen the first time, because I would never have been able to pinpoint the problem. This time, I knew which chip was suspect.

The trouble is, I don't know how I fixed it. I re-soldered the pins of that suspect chip, and it didn't help. I poked at the bus wires and resistors, and it didn't help. But then, magically, it worked! I have no idea what I fixed, but I can only imagine that my futzing with it broke some short I had introduced. It hasn't given a lick of trouble since then (two weeks ago or more), so my faith is growing.

In conclusion, I suggest that rank amateurs not do this, but that middleweights should give it a try -- especially if they have an expert or two around whom they can ask if they get in trouble. For experts, this should be a piece of cake. In any event, you don't have to pay $150 for somebody else to do it; just $50 for the chips and a few hours of your time. Naturally, if you have the bucks, and don't want to take your ST into your

own hands, find a pro, or a friend who has done it.

Don't bother "poke-blasting" the memory controller ("MMU") address
space. There's nothing interesting there. If you don't believe me,
then go ahead.

The 68000 makes a bus request every 4 cycles. This means that there are
3 other cycles available for doing stuff. 2 of these cycles are used for
video DMA. 1 more is used for disk DMA.

Now, it is NOT true that the 68000 makes a memory access every 4
cycles (I lied.) The processor is given a window every 4 cycles,
and it is stopped if it makes a request that is out of line. It
quickly falls back into step. This means that the processor loses
cycles occasionally, but very occasionally.

(If you don't beleive me, go ahead: write some assembly language
benchmarks and count cycles. THEN you can start talking numbers
about "occasionally".)

Multiport RAM on a consumer machine? Yick. How much does that COST?

A couple of general questions for the group: the January BYTE hinted
that Atari was coming out with an 8 slot expansion unit for the ST
in the first part of '86. Any truth to this? Anyone know anything
different?

Also - this may be a moot point, since I already sent in my order
two weeks ago - does anyone know anything about Metacomco?
Specifically: I am curious about their Macro Assembler, their
ISO PASCAL standard ("Meta Pascal"), their screen editor and their
linker. Any comments on their stuff would be GREATLY appreciated.

For anyone who is curious: I am the proud owner of an IBM XT, and I
just recently purchased an Atari ST. I am impressed so far by what
I can get it to do - which isn't much since I am lacking compilers,
assemblers, and other goodies. They are on order, but mail order
stuff takes such a depressing long time to arrive.

I also purchased one book from ABACUS Software - it is AMAZINGLY
INFORMATIVE - and plan on purchasing another. (One of these books
has already been reviewed here.) They are also cheap. ($19.95 apeice,
as opposed to the $300 for the developer's kit from Atari...)

Since this is my second computer, I don't want to spend a lot of
money on it right away....

...it does, however, look like fun....

Organization: Electrical Engineering Department , Purdue University
Lines: 77
Keywords: Pascal 520ST OSS

Product name: Personal Pascal

Price: $70.30 (including tax, from Von's Computers, W. Lafayette, IN)

Vendor: Optimized Systems Software, Inc. (OSS, the guys who made ACTION!)
1221 B Kentwood Avenue
San Jose, CA 95129
(408) 446-3099

Introduction:
I purchased Personal Pascal from my local dealer (Von's Computers, West Lafayette, IN) Thursday at lunch and have been playing with it in my spare time ever since. This package has got to be one of the best values for those of you who, like myself, have not purchased the $300 development package but want to do GEM programming on the ST. It generates compact, fast code and makes using GEM easy through many library procedures to do windows, etc.

Description:
The package includes a non-copy-protected disk with a "system manager", simple editor, compiler, linker, and complete libraries for various pascal functions as well as a complete set of GEM interface functions. Along with this comes a rather complete manual of 200+ pages, which describes: how to use the editor, compiler, and linker, describes all of the included library

functions, describes windows, menus, alert boxes and event management with GEM as well as a short description of their implementation of Pascal (right down to notes on how they store the various variable types!)

On the disk they have included several demo programs to get you started. These all compiled and ran with no trouble. The "system manager" provides a handy GEM interface to the compiler, editor and linker. Compiler errors pop-up in an alert box giving you the option of jumping into the editor to fix things. It's simple enough to use that I don't think I ever even looked at the section of the manual which descibes it!

Bencharks:
Although I've not extensively tested the compiler & linker here are the compile times and sizes for my clock program (which follows in the next two articles) and a simple "hello world" program. All times are for compiles from a single sided floppy. "checks" refers to the optional compiler run-time checking. The times were done with a wrist-watch stopwatch and so are probably off by a second or two:

program:	hello world	clock	
compile time			
w/checks:	0'36"	na	(' = minutes, " = seconds)
w/o checks:	0'36"	1'25"	
link time			
w/checks:	0'45"	na	
w/o checks:	0'41"	1'05"	
Total			
w/checks:	1'21"	na	
w/o checks:	1'17"	2'30"	

File size			
source:	64	9672	(sizes are in bytes)
.prg files:			
w/checks:	4179	na	
w/o checks:	1361	23637	

License and support:
The OSS license is simple. Sign the enclosed form, and put their message in your program where the end user can see it. No fees, no fuss. As for support, the package comes with an ID number which you use when calling either their phone line (not an 800 number) or their BBS. They seemed very eager from their documentation to be sure you could reach them if you had any questions. I've not had to contact them yet so I can't comment on how good their assistance is.

Overall Impression:
I've extremely happy with Personal Pascal. Over the weekend I've written my first GEM program which I've posted in the next two messages (once as source, once as uuencoded binary) so you can see just how easy it was to do. My major complaint? Not enough room on the floppy. Only about 55k remains after you clean off the demos. Other than that I'd say this is a great way to start programming your ST in GEM inexpensively.

I suspect that the "UNIX workstation" would be more like a terminal to
a Unix system. Remember the Blit? Rob Pike and Bart Locanthi's
unreleased bitmapped terminal which AT&T management aborted into the
Teletype 5620? I've heard of projects that put the Blit software into
a ROM cartridge for the Atari without much trouble.

In article <789@decwrl.DEC.COM> you write:
>
>1. Does anyone have experience with the Modula-2 software
>   developed by a British group?

Yes, it's a very complete system, with 6-pass compiler, linker and
screen-editor. However, it has some disadvantages since Modula-2
uses many files for IMPLEMENTATION and DEFINITION modules, so it
takes much disk space and time to compile and link a simple
application.

>
>2. What does one get in the development package offered
>   by Atari for $300?
>

You get:
i.   The C-compiler and pre-processor (cp68.prg, c068.prg, c168.prg)
ii. The linker and relocator (link68.prg, relmod.prg)
iii. A utility disk (dump68.prg. size68.prg, command.prg, etc.)
iv. The Resource Construction Set (rcs.prg)

>   capabilities of the 520 ST.

The Basic implementation is very much Microsoft compatible. However,
I find it somewhat slow, because of the use of the GEM environment.
I don't often use it, but that's maybe 'cause I'm not a Basic fan.

>
>   I've never used 'C' before, does anyone out there recommend
>   it, and why?
>

I recommend it to you when you have experience with a Pascal-like
language, and if you have no objections against less structural
and more assembly-like statements. Then C would be a perfect
combination of a structured language and a development tool for
you. Other languages you can use for developing purposes are
TDI Modula-2 (described above), and OSS Pascal and 4xForth, which
I haven't seen but seem to be very powerful.

I'm looking for information on the use of the 1027 Printer from Atari
together with a word processing program (Public domain or Commercial).
I would appreciate ANY comments on this topic.

Also for those of you who own 1027 printers: where do you buy replacement
ink rollers for the printer ? They appear to have been specially
designed for the 1027. Are you forced to re-ink them by hand ?

Please reply to me at the following arpa-net address.

Thank you.

Nf-From: iuvax!franco   Feb 3 09:09:00 1986

I am looking for a RAMDISK for an ST which satisfies the following
requirements:

1. Grows and shrinks automatically. Growable to at least 360K and hopefully
   higher (to 700K would be great).

2. Works on an upgraded (to 1 MEG) ST exactly as well as on a regular ST.

3. Allows 4XFORTH applications (ex: STTALK) to be run with no problems.

4. Works on an ST with TOS in ROM (with and without upgrade).

5. Will work on 4MEG ST (when the 1MEG DRAMs are readily available).

6. Allows the ST to function exactly as it would without the RAMDISK
   (examples: does not crash computer when changing resolution
              does not affect fonts...etc...)

7. Is installed as a desk accessory.

Information leading to the acquisition of such a thing, if it exists, would
be greatly appreciated.

>

I've used streams with no problem:

```
     OpenStream(handle,"foobar.doc",READ,reply);

     However, the same thing done with the printer acts weirdly:

          OpenStream(handle,"PRN:",READWRITE,reply);
          (* reply is -3 - "unknown command" *)
```

Having posted a glowing review of TDI Modula-2, I am now starting to find
a few bugs. When I have a complete list, I will post a follow-up.

I think the problem you are having is probably more related to the fact that
you have a Rev. A board.  I just put in the ROMs on Rev. B board and I still
have 1 MEG of memory that works just fine.  Are you sure you have the final
ROMs and not the EPROMs that were available early?

I have Action itself + the Toolkit. I've also written a bit more onto it, including a proper real number handler for PrintF() & 1020 dump,full featured Life etc. I WANT TO TALK TO SOMEONE!!!!! I've been Atari for 4 (count 'em) four years now and I need a full list of bugs,sources etc. I was very cheesed off to find that negative steps don't work.

COMPUTE! Magazine's "product description" of the 520ST, I believe in the
October, 1985 issue, described the CPU/DMA interface to memory.
What they described sounded like essentially a time-multiplexed form of
dual-porting: neither the CPU nor the DMA controller ever (much) has to wait
for memory access. (They pointed out that because the 68000 accesses memory
asynchronously, it will OCCASIONALLY happen that it will have to wait, but
so rarely that you will never see it in terms of throughput.)

RE:
I would appreciate it if someone could give me the name and addresses
of any Atari magazines that provide useful info into the ST.

Here is a note I put on the net back in October. I have no idea
as to the current state of the magazine.

A friend just loaned me a copy of a magazine he found out in
California:

S/T Sixteen/Thirty-Two Applications
The ATARI 520ST Journal

Partial table of contents:

1 MEG Upgrade for your 520ST (same article posted earlier)

Departments:

MIDI Beat Discusses the MIDI interface.
A Step FORTH Not a column about C.
FORTH Tone Dialer A phone dialer program.
Purposeful Pascal The Pascal column.

Reviews Etc.:

Unacceptable Software The didn't review a dirty joke program
Available Software Currently available software titles
Desktop Helping users deal with the interface
Software Reviews
Chat; Flip Side; Hippo Computer Almanac; M-Disk, ram-disk
emulator; A Mind Forever Voyaging; Mudpies

This is not what you would call a large budget magazine. I found the
print quality a bit less than the "Dtack Grounded" (R.I.P.) newsletters.
It is printed using dot matrix printers. One hundred copies of the first
issue and 300 hundred of the second have been printed.

If I were going to get an ST, I'd probably try it for a year. No flashy
color graphics. No overdone hype either.

If you want to check it out the details are:

S/T
Sixteen/Thirty-Two Applications
10760 Hwy 116
Forestville, California 95436

$5.00 for the current issue
$25.00 for 6 issues

$10.00 for the current disk issue
$50.00 for 6 disk issues

Is there any source of compilers, assemblers etc. for the 800XL which produce
relocatable object code and can be used with a linking loader? I would
especially like to be able to develop a library of routines and have the
loader link only those routines that were actually referenced, a la the
"librarian" on the PDP-11. (Ah, my wife always was suspicious of those
late-night sessions "with the librarian".)

Any assistance will be greatly appreciated.

(i believe this is correct) the font-maker worked by replacing the
'standard font' in TOS with its own by changing a vector, with TOS
in rom guess what (hint: the RO stands for read-only (:-))

Does anyone have the Atari game Alternate Reality and know where the guilds are? I've found most of the other buildings (shops, inns, taverns, etc...) but only 2 guilds. (If you do know, please reply by mail). Also, what do you need in order to join a guild?

I sent a bogus description of the ST's bus cycle architechure to this list. I apologize. This morning I collared one of the hardware people here and shook the real description out of him:

There are two 250ns windows. One window is for "static" system requests (video DMA and memory refresh). The other window is available for disk DMA, blitter DMA, and processor accesses. Refresh cycles are done during horizontal and vertical blank (and take, say, 5% of the first window). When the first window is not being used, it is available to fill requests that would otherwise go to the second window.

I don't know exactly how much bandwidth is used by memory refresh cycles,
but it is low. 5% is probably not too far off.

Please forget my earlier misdescription of the bus architecure ....

I am using the Kermit program in Action! available from the archive. I
can successfully transfer short files, but am having trouble with one
file in particular: KCOM1030.ACT. I don
I do not need this file to run, as I am using an 850 interface, however
in the interest of completion I would like to get it. Xmodem transfer
would work, (although I would have to translate CR/LF to ATASCII EOL),
but that still doesn't explain why kermit will not transfer this file.
I presume this is because of the file's size. Anyone have any ideas?

I have a Sanyo 9" composite video monitor and would like to buy an
Atari 520ST. Can anyone tell me if this monitor will work or do I
have to buy the Atari monitor? If it is just a problem of connectors,
I can fix that. This monitor has been used on IBM Pcs and an Apple][.
Please mail replies to me. Thanks in advance.

1. Before I order back issues of ANTIC with S.A.M. programs in them:
    Is S.A.M (software automatic mouth) a published program in ANTIC,
    or is it commercial only, and the ANTIC programs just utilities?

2. I am going to type in (!!!) Speedscript 3.0 from May 85 Compute!
    and would like to know if there were any corrections or updates in
    later issues of Compute! Also, does anyone know if back issues are
    available? I looked through the mag, but didn't see anything about it.

Thanks.

Has anyone ACTUALLY obtained a composite video output from
somewhere within the ST? I have heard speculation that the
such an output SHOULD be available (indeed the circuit board
photo in Byte looked like it contained a spot for an RF
modulator) but I have not heard from anyone who has actually
connected a composite monitor.

In my appeals to the net for sources of public domain word processors, only
one has appeared, namely Speedscript which apparently was published in 1985
in Compute Magazine. Aside from typing it in or sending $12.95 to Compute
does anyone know of any other way to get it ? Is it available on Compuserve
or for that matter any other bulletin board ?

Please reply to ajb@mitre

I have been trying (unsuccessfully) to switch my disk drives
to and fro from double density. It is easy to do from a
DOS that does it. (eg. TOP DOS or MYDOS).

What I want to do is to be able to do it from my program.
I write everything in ACTION so assembly or machine code is
quite acceptable. I will even translate it from BASIC string
machine codes if I have to. Help!!!!

PC/InterComm from Mark of the Unicorn (617) 576-2760 does an excellent
VT100/102 emulation. I have used it with both Unix and VMS. The EDT
keypad mode works fine, as do the Unix editors with vanilla termcap
entries.

Also in the package are Kermit and Xmodem file transfer, easy-to-use
setup menus, and some other nifties.

Current price is $124. I got it from a local Atari dealer.

A co-worker has also used it dialing in to an IBM mainframe, with
their VT100-translation software.

Keywords: I did it!

Earlier, I read a posting that suggested that ST's with the metal shielding soldered shut may not accomodate more RAM. Well, I only let it panic me a bit and tried to install the RAM anyway. I succeeded in installing the extra RAM and there is plenty of room for the piggybacked chips in my ST (my serial number is in the 10390xx range).

The installation (using Joe Augenbraun's instructions) only took me 2 1/2 hours. I have to qualify that; several years ago I represented the United States in the "International Skill Olympics" in Industrial Engineering.

Suggestions:
- Edit Joe's instructions so you can read them while working (I tended to skim his instructions and inadvertently leave steps out).

- Don't go to Radio Shack for 68 ohm 1/4 watt resistors (they don't have them) and DO use 1/4 watt resistors.

- Remember which screws go where: there are three lengths of screw.

Then again, I do work a bit too quickly for my own good.

I guess my current question is: how am I gonna get the TOS ROMs installed now?

Good luck!

H. Todd Fujinaka, whose warranty is voided

~~~~~~

are you mad ? is richard ? all their development is done on the ST
and if the bouncing ball demo isn't programming on the ST then i
don't know what is!!!!!

My local Atari users group is planning an introductory course for
forks who got an Atari 8-bit computer (for Christmas) and don't
know what to do with it.

The "course director" is interested is a product called Basic
Building Blocks by Micro Education Corp of America, copyright 1983.
But it appears to be out of distribution. Any information about
the address of the company or availability of the software would be
appreciated.

Additional suggestions would also be gratefully received.

Sincerely,

*** REPLACE THIS LINE WITH YOUR MESSAGE ***

26 january 1986

i just had TOS on rom installed in my ST, the roms, installation and ny state taxes brought the total to $26.88. this frees up about 190k of ram. it should be noted that the desktop and desk accessories must be on the disk from which you boot. the standard desk accessories take up about 22k. with the disk TOS i could make a ram disk (using M-Disk from Michrotron) of about 80k, now i can make one with ~260K.

there are two interesting side effects of the rom TOS. the colors on the desktop (i haven't had time to check elsewhere yet) are distinctly "richer". in addition some of the moire patterns that plagues

the color monitor have been eliminated or reduced in intensity.

before leaving the dealer he did point out one "bug" with the rom TOS. font-maker software from ANTIC would work under the disk TOS but NOT with the rom TOS. also i've experienced some problem with saving a new desktop to disk; i won't declare this a bug yet until i've played with it a bit more.

you can still boot using the disk TOS if you like.

The following is an assortment of my observations on 520ST software.

1.) a number of people have asked about "macwrite-like" word processors. i've been using 1st Word which is from a british firm. it's pretty nice but it's not a full-fledged "macwrite". i've been unable to figure out how to output something using double spacing. the program operates in a "document" or strictly ascii mode. the annoying thing is if you save some text as ascii you can't convert it back into a document and use the reformat command.

2.) the ramdisk package from Michrotron (M-Disk) is nice for one drive people like me since i can copy 200k to the ramdisk and from there to another floppy. it cuts down on the number of disk swaps necessary to back things up.

3.) ST-TERM from QMI is a weak attempt at terminal emulation. it fails miserably with vi. i've been unable to make it properly understand xon/xoff. and on uploading from my atari to a mainframe my screen fills with garbage instead of the text that is being transfered. it seems to carry off the transfer okay but i wouldn't want to depend on this product. i would like to know if any of the VT100 emulators make use of the vt100-like keypad for use withe edt on a vms/vax? also how about a tektronix 4010 emulator. i have in mind PCPLOT for the ibm pc, it is both a vt100 and a tek4010. if you don't need to upload or download the atari builtin vt52 is pretty good.

that's all for now!

<ritual sacrifice>

An addendum to randy's response to stephen's question:

(If you run programs from both command.prg and the desktop.)

I've found it's most convenient to use the .prg extension and use the Install Application option to specify the program type (TOS or TOS-TAKES-PARAMETERS). Command.prg does not recognize .tos or .ttp as a default program extension like it does .prg. For example, MicroEMACS would be named me.prg and be installed as TOS-TAKES-PARAMETERS.

Be sure and save the desktop after installing an application!

Btw, does anyone know if there is a limit on the number of installed applications? (Or what the practical limit is?)

I have just completed the 1 meg memory upgrade on my 520st using a 1 meg upgrade document taken off of a bulletin board in Florida. I found the document a little difficult to follow, and there was one major mistake in it. I am not sure if there are different versions of the document (I think they all derive

from a posting that I saw on INFO-ATARI a while ago). Rather than sending a correction, I decided to rewrite the whole document. I hope that this will help those people who have yet to make the upgrade. The document below is derived from the version of the memory upgrade that includes the 68 ohm resistors (the one that reportedly was tested by an anonymous engineer on Atari's development staff). My PC board has "REV. B" written on it. I'm not sure what the different rev's are, but I'll give warning to be careful about following these explicit instructions if your board is not REV B.

A couple of side notes:

1) I'll be happy to answer any questions about the memory upgrade (another public service) as long as the volume isn't too high. I'm augenbra@udel-scrooge.arpa

2) When I followed the (wrong) instructions that I got from the bboard the machine did not boot. As a matter of fact the screen would turn on in white or blue for one second and then go blank again. I didn't even get the boot screen. I then figured out that the instructions were wrong and made the corrections that were necessary and the machine booted. The moral is that following the wrong instructions (for anyone out there who did) is not fatal to any component, and you can get things working again by correcting the mistake.

3) I only upgraded one machine, using those old instructions. The moral of this is that I've never used the document below and it could contain mistakes. I'll read it through pretty well, though.

4) I take no credit for this upgrade. I used some of the text from the original document word for word. I forget who posted the original instructions, but he deserves any credit.

cut here----------

1 MEG MEMORY UPGRADE FOR THE 520ST

WARNING: This will void your warranty, etc.
WARNING2: This upgrade is not for beginners. You really need to have the right tools and know what you are doing to get it right. Also, if you damage the machine with this upgrade it is unlikely that you will be able to find anyone who will fix it. This upgrade involves cutting three traces on the board, so you couldn't just take out the new chips and try to send the machine back to Atari. OK, enough scare.

Tools & components needed:

16 256K * 1 RAM chips, 150 ns access time type, e. g. NEC 41256C-15 (available at Fry's Electronics, Sunnyvale, CA for $2.77 ea.)

6 68 ohm 1/4 W carbon film resistors, 10% tolerance. I used 1/2W, but I was cursing the whole time. This is because 1/2 W are really too big, so use 1/4 W if you can.

A decent soldering iron. Needs to have a tip that is the same size as an IC pin or smaller. A Weller temperature controlled station would be perfect, but I got along with my Ungar Princess.

Good quality resin core solder (thin)

A few feet of thin (24 guage is good) insulated wire

A few feet of solid copper tinned bus wire. 22 AWG would be good, I used 24 AWG with no apparent problems.

Solder sucking equipment

Normal hand tools (screwdriver, pliers, etc)

A steady hand and self-confidence

Explanation of the modification:

U15 is a memory controller chip (Atari calls it an MMU even though it isn't). It goes inbetween the 68000 and DMA devices and the memory. Thus all communications to memory is done through this chip (someone correct me if I'm wrong). The chip knows about two "banks" of memory. Each bank consists of 16 chips. These chips may be 64K, 256K, or 1M DRAMs. I'm not sure if you can have different types of chips in the different banks. As shipped, a 520ST has one bank of 256K DRAM's. These chips have all of their address lines in common. The RAS line is also common to all chips. There are two separate CAS lines, one for the lower 8 chips, and one for the upper 8 chips. All of these lines come directly from U15, the memory controller chip. There are also 3 lines available from U15 that are currently not connected at all. They are the RAS line and two CAS lines for another bank of memory.

We are going to add bank 1 (the original chips are bank 0). The new chips will be "piggy-backed" onto the original chips. All of the pins from the new chips will be connected directly to the respective pin of the original chip that it is piggy backed to except for pins 4 and 15 which get wired to the U15 bank 1 RAS and CAS. Thus the new chips share address, data, power and ground with the old chips.

All RAS pins of the new chips are wired together and will be supplied with the "RAS1" signal generated on pin 18 of U15. The CAS pins of the 8 new high order byte chips are wired together and are supplied with the "CAS1H" signal from pin 22 of the memory controller, and the 8 new low order byte chips are wired together and supplied with the "CAS1L" signal from pin 21 of U15.

Reference:

The existing memory chips are numbered from U16 to U45. There are some gaps in the numbering, but they are numbered in increasing order. The high order group, from MSB to LSB consists of U45, 44, 43, 42, 38, 34, 33, 32. The low order group from MSB to LSB consists of U30, 29, 28, 25, 24, 18, 17 and 16. One of the groups is used for even memory locations and the other is used for odd memory locations; I'm not sure which is which, though.

How to go about it:

Step 0: Read these instructions through, and do not apply power to the ST if the mod is half in.

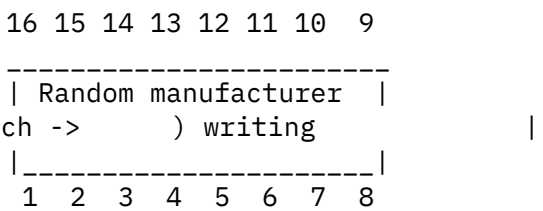
Step 1: Open up your 520ST, pull off the keyboard connector and remove the main circuit card from its top and bottom shielding. Make sure to remember which screws go where and note the keyboard connector orientation.

Step 2a: Desolder all of the capacitors next to the existing RAM chips and make sure that the holes are clear enough for the cap's to go back in easily. This step is necessary so that you have enough space to solder the new chips to the old chips.

Step 2b: Clear away any solder splatter that is sticking in nasty places on the component side of the board. This will soon be real inaccessable.

NOTE: If you damage the PC board you better fix it before going on. Things start becoming inaccessable now.

Step 3a: Take a RAM chip, and bend pins 4 and 15 (RAS and CAS) so that they are sticking up (yes a 180 degree bend). Use whatever care is necessary to keep the pins from breaking off. A rounded bend might be necessary. For those of you with poor memories (organic, not silicon), here is where pins 4 and 15 are on a 16 pin DIP. Chip is as seen from the top.



Step 3b: Place this chip on top of one of the existing RAM chips, put it on the leftmost or rightmost, whichever you prefer. Bend the other 14 pins so that it has a snug fit on the RAM chip. The bottom of the new RAM chip should be touching the top of the existing RAM chip. Now solder the 14 pins that aren't sticking up on the chip. Don't overheat, everything is static sensitive, etc.

Step 3c: Repeat 3a and 3b for the other 15 chips. No one ever said that this

was going to be fun.

Step 4a: Remember those capacitors that you spent an hour taking out? You guessed it. Now you have to spend a half hour putting them back in.

Step 4b: Generally clean up the board. Look for bits of sticking solder debris.

Step 4c: Take a break, eat lunch, have a beer. You're only about half way there.

If you've done everything right so far your work should look like a combination of piggy-backed RAM chips and a bed of nails.

Step 5a: You must now take a piece of bus wire and cut it to the length of the chips. You don't need any extra length since the connection from the bus to the memory controller will be made to the middle of the bus, in a "T" fashion. Take this wire and solder it to all of the pin 4's, forming the RAS bus. Cut off any part of the IC pins that extend above the top of the wire. The wire must actually be touching the RAM chips. This is so that the wire doesnot touch the metal shielding above, i.e. so that we have maximum clearance.

Step 5b: Take another piece of bus wire and cut it to the length of the chips and wire it to all of the pin 15's. Once again make sure that it is as low as possible, actually touching the tops of the IC's. And cut off any part of the IC pin that extends above the top of the wire.

Step 5c: Cut the pin 15 bus wire in between U30 and U32, thus making the 16 chip pin 15 bus into two 8 chip buses. These are going to be the two new CAS buses.

You now have 3 buses extending above piggy-backed RAM, 2 of the buses are 8 chips long and one of the buses is 16 chips long.

Step 6: Orient the 520ST (REV B) PCB so that you are looking at the solder side (non-component side). with the row of d-rams nearest you. Find the double square pattern of pads at the 68-pin socket of the memory controller, U15 (3H-2119). The following is a guide to locating the six memory controller pins necessary to complete the wiring. It is not as convoluted as it looks. The socket is numbered CLOCKWISE when looked at from the bottom of the board (this is the mistake that I saw in another version of this document; it said counter-clockwise). The sequence starts with pin 1, the square pad (look closely) in the middle of the bottom outside row. The sequence, moving clockwise from pin 1, first on the outside square ONLY: (NOTE: the sequence ")(" means to make a 90-degree turn clockwise, e.e. around the corner)

1,3,5,7,9)(10,12,14,16,18,20,22,24,26)(27,29,31,33,35,
37,39,41,43)(44,46,48,50,52,54,56,58,60)(61,63,65,67

The sequence, moving clockwise along the inside square only, and starting with the left side of the bottom row:

62,64,66,68,2,4,6,8)(11,13,15,17,19,21,23,25)(28,30,32,
34,36,38,40,42)(45,47,49,51,53,55,57,59

Six 68 ohm resistors are used in the upgrade. 3 go to the RAS and CAS lines of the new bank, and 3 go to the RAS and CAS lines of the original bank. These series terminating resistors minimize overshoot which may damage BOTH BANKS of memory if ommitted. The upgrade will not work right if you try to get away with just the 3 for the new bank. So bite the bullet and go for all six.

Step 6a: Solder a 68 ohm resistor to pin 18 of U15, RAS1. Solder a 24 AWG stranded wire from the remaining end of the 68 ohm resistor to the pin 4 bus (RAS) of the new d-rams.

Step 6b: Solder a 68 ohm resistor to pin 22 of U15, CAS1H. Solder a 24 AWG stranded wire from the remaining end of the 68 ohm resistor to the pin 15 bus (CAS) of the new U45, 44, 43, 42, 38, 34, 33, 32.

Step 6c: Solder a 68 ohm resistor to pin 21 of U15, CAS1L. Solder a 24 AWG stranded wire from the remaining end of the 68 ohm resistor to the pin 15 bus (CAS) of the new U30, 29, 28, 25, 24, 18, 17, 16.

The other 3 resistors go in series with the RAS and CAS lines to the original chips. This means that you have to cut three traces.

Step 6d: Find the traces leading from pins 6, 7, and 8 of U15 to the RAS and CAS lines on the original chips. On my board these traces ran on the component side of the PCB from the memory controller socket downward. (For this discussion the PC board is oriented with the component side up with the memory chips towards you). My board has some of the memory controller pin numbers printed on the board, specifically the numbers 1,9,10,26,27,43,60. The traces are three traces that run together straight for about a centimeter below and to the left of the pin 9 number on my PC board. They run together for maybe 2 cm altogether, but they are straight and close for only 1 cm of that. When you think you've found the right traces scrape off the green stuff and get down to metal and check your findings with an ohmmeter. If you are not right, find the right traces. If you are right, cut all three traces. That's right, make it so that there is no connection.

Now we will reconnect the three traces, but with 68 ohm resistors instead of a 0 ohm wire.

Step 6e: Connect one side of a 68 ohm resistor to pin 7 of U15. Connect the other side to the board-through solder pad that is to the left of pins 1 and 2 of U16. You will note that this connects directly to left-most of the three traces that we cut.

Step 6f: Connect one side of a 68 ohm resistor to pin 6 of U15. Connect the other side to the board-through solder pad that connects to the middle trace that you cut.

Step 6g: Connect one side of a 68 ohm resistor to pin 8 of U15. Connect the other side to pin 4 of U16. This is the last connection.

Step 7: Sit back. Use Brain. Do you feel confident about the quality of your work? No mistakes? No resistor leads shorting PC board metal? No solder splatters that haven't been taken care of? Applying power with errors might make your ST into a decorative, non-functional piece of art. OK? Either rebuild your ST into its shielding and cabinet or, or put it onto a surface clear of wires and solder remains (the better way. No way that shorting to shielding is a problem) and connect it to the mouse, monitor, power supply and disk drive. Boot it. If it boots your probably there. Test if the new memory works by looking at the phystop variable ($42e) with SID or BASIC. It should read $100000. Also note that memcntlr ($424) now holds 5 instead of 4, and that v_basf_ad ($44e) now holds $f80000 (screen bitmap origin). Or you could try a single drive copy and check that it gets the whole disk in one buffer instead of 2.

In case of difficulty:

    If the new memory does not seem to exist, try depositting and retrieving words in locations $80000 and up (1/2 meg decimal). If bit errors occur the ST bootROM did not detect the extension (it checks all bits of 512 locations by testing a pseudo random sequence before accepting a memory bank). Check which bits are screwed up and look in the reference part of this document and try to correct the problem. Note that if you get $84 $80 $84 $80 in all memory at $a00000 and above it means that you didn't cut the traces on the board right. Check those traces with an ohmmeter across the resistor. It will read 0 ohms if the traces weren't cut right.

    If the machine doesn't boot (doesn't even give the boot screen) you either made a wiring mistake or burnt something out (or I made a documentation mistake;If there are any differences between this document and the older one that you have seen besides the clockwise vs. counterclockwise thing, the older one is right, because that is what I wrote this one from). Look for wiring mistakes, have some rational human being check your work. Look for insidious bits of solder or wire debris. If you are determined that you burnt out something, try the memory controller first since it is socketed. Find some benevolent soul with an ST and try your controller in his. If that works, my guess is that you fritzed the memory, and you should either desolder it and test it in an IBM PC or something or cut it out and put in new memory and call it a $100 loss. You could cut your losses by buying a memory expansion card. I understand that they require you to cut out the existing chips. Sorry I don't have any better idea.

What do I do with it now that I have it:

    There is a PD 360K ram disk program for a 1 Meg expanded ST. I haven't tried it yet (I just put the memory in 2 hours ago, and that 2 hours was used for writing this document), but that's why I want the memory.

Has anyone out there on the net figured how to get the new 130XE version of SynCalc(R) to load? I recently purchased it and am trying to load it on a normal Atari system. I.e. 130XE with a 1050 disk drive. I understand that it (SynCalc) is extremely sensitive to drive speeds due to the copy protection scheme. I have three different 1050 drives, none of which will load SynCalc with any degree of reliability. When I learned of its susceptibility to RPM, I fine tuned all three. I have one drive set so that it consistently is at 288 RPM which is the nominal RPM for a 1050. The other two drives are set between 286--290 RPM which is the range allowed. Not one of the three drives will work -- I have set up each as drive 1 with the other two off line to make sur and not one will consistently load up. Is there a magic RPM that SynCalc likes? Like maybe the high end (290 RPM) or the low end (286 RPM) or some other RPM?

If there is anyone from Synapse on the line, I would appreciate something from the horse's mouth, as it were.

Thanks in advance,
--Bill Dippert--

    Just thought I would inform everyone of a nifty bit of information I picked up over the weekend. You can copy Atari ST diskettes on the Amiga by using the IBMTransformer and the normal IBM disk copy routines. The ST uses straight IBM format on 3 1/2" disks it seems!
    From your collector of useless(?) trivia,

---------- lineater offering ----------

I have recently picked up the book "Atari ST Internals" by K. Gerits, L. Englisch, and R. Bruckman; published by Abacus Software, cost $19.95. The book covers a wide variety of subjects in its 446 pages, including the integrated circuits (except the miscellaneous TTL parts), the hardware interfaces, and the operating system. Included in the book is a listing of the 20 June 1985 BIOS. In brief, it is a good addition to the developer's kit, but no substitute for the documentation contained in the kit.

The book is divided into three chapters, The Integrated Circuits; The Interfaces; and The ST Operating System. The first chapter is about 60 pages long and provides cursory descriptions of each of the major circuits in the ST. The second chapter provides a 34 page description of the interfaces available on the ST including the pinouts of the connectors and a schematic diagram of each interface (except the cartridge). The final chapter takes up the main portion of the book and is contains descriptions of GEMDOS, BIOS, XBIOS, Line-A calls, the exception and interrupt handling, the VT52 emulator, the system variables, the 68000 instruction set and addressing modes.

----- start of long! review ------

The first chapter gives very short and incomplete descriptions of the custom chips (Glue, MMU, Shifter, and DMA) -- apparently the authors didn't have any more info from Atari than we do. The descriptions of the standard parts are more complete, but less than one could obtain from data sheets. Information on programming the standard parts (including the sound chip) are provided. A diagram of each chip is included, the only item missing is the notch in the DIPs and the bevel on the leadless chip packs. These diagrams might help clear up some of the memory upgrade confusion.

The second chapter provides a diagram showing the pinouts of the connectors and a sort-of schematic. The keyboard description is probably better than the summation of the various documents provided in the developers kit. It has a listing of the keyboard commands and a program for dumping the keyboard ROM. The diagram of the codes returned by each key is especially nice. The manner in which the chips are used is presented in this chapter, giving an insight into the capabilities and limitations of the ST. An example is that the cartridge port cannot be written to (even if you bring out r/w lines) because the Glue chip will generate a bus error.

The third chapter is the real reason to buy this book. The discussion of the GEMDOS calls is probably better than the GEM DOS Spec. provided with the developer's kit, but the examples are provided in assembler, not using a C language binding. This is probably not a major problem, as the bindings given in the GEM DOS Spec. do not match the include file osbind.h anyway. The descriptions of the XBIOS calls include the C bindings, but once again the examples are given in assembler. This section is roughly the equivalent of

"A Hitchhiker's Guide to the BIOS" provided with the developer's kit. The real win in this book is the section which describes the graphics calls. Here 14 of the 15 "line-A" calls are described. The descriptions and examples are much clearer than "The Long-Awaited Line 'A' Document." The exception and interrupt sections provide in one place information which is scattered throughout the developer's kit (I think, I haven't found all the stuff in the kit yet). The listing of the system variables is more descriptive than the Guide, but not as extensive in the interpretation of values. One thing to note is that the value of _hz_200 ($4ba) is correctly reported (as opposed to the value $4bc given in the Guide). The next section is a listing of 68000 instructions, ok for getting the general idea of the BIOS listing which follows, but you won't be an assembler programmer after you're done reading it. The BIOS listing is old, and represents the version which was provided when the ST was first made available in the U.S. The listing suggests a way to find out what the date of your version of TOS is: using SID find the value of _sysbase (longword at $4f2) display the beginning of the os and examine the seventh longword. It should have the date (mine has $11161985). [If somebody has the TOS ROMs, please post the result.]

In conclusion (finally!), I would recommend this book to developers and even to non-developers. It provides a reasonable description of the hardware and software. The major shortcoming is the lack of AES or VDI documentation, but that is alluded to by the very last printed page -- an ad for "GEM Programmers' Reference Atari ST," among others. One missing item is an index. This would have been real handy, but probably added an additional 20 pages.

My brother and his kiddie friends used to write crappy programs
like the "Grape Stomper" one you mentioned and sick them on each
other when he was in high school. The only way to protect yourself
from such childish pranks is to back up your disks before you run
programs on them and to write-protect them.

> more than 512K of memory, but this sort of shenigans is typical of Atari.

Speaking of shenigans, it appears that most if not all computer companies
stoop to such standards. Years ago I purchased a 16k pet with the idea
of upgrading it to a 32k. Upon opening it up I discovered that the board
had been drilled through with 3/8" holes to destroy that area of the mother
board where the extra memory chips would go. Nice huh?
By the way, and I hope Commordore is listening, I was able to upgrade not
only mine but other peoples as well.

~~~~~~~~~~~~~~~~~~~~\ lineater, \~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

well said Erik, unfortunately Atari runs VMS inhouse so getting them
on the net may a little difficult. Does anyone out there (esp. at
DEC) know of a way to get on the net from VMS? someone from Atari
does watch the net but he does it from another machine and he
does not really take an active hand in the net, i wonder if he might
consider "coming out of the closet (:-)". You listening ?

I heard a rumor that there is a program that gets the time
and date from a prometheus promodem and puts it in the 520ST's clock
registers. Can anyone point me to a BBS or other sources
for this program? (I assume it's public domain).
I looked on Compu-serve (where I heard the rumor) and I couldn't
find it anywhere.

Thanks in advance,
R. T. Bradstrum

After receiving a lot of requests asking where I got the $25 850 and
$75 disk drives I did a little investigating to see if I could remember
the name of the place.

The store is called San Salvage and is located in Nasau county in Long
Island, NY. I think the town might be either Levittown, or Hempsted.
If I had know there would have been so much interest, I would have
bought some extras. I'm not sure how often they carry them but I do
know that it wasn't a one time special. The store deals with items that
have been discontinued, or overstocked and sells them for cheap. (something
like cut-out records). From my understanding at the time, they will
continue getting shipments of atari products. Hope this helps.

     Kurt*

It appears that the atari sig has missed the discussion that i saw on the
info-cpm mailnet regarding trojan horse programs. Never try out a new non-
commercial program on an unprotected system. Be able to disconnect your

Wini or have a fresh back up on the shelf. Some of these numbers have been really insideous, like worms, slowly eating away files, or worse yet subtly corrupting them, so that by the time you notice even your back ups were damaged. I seem to recall that a PD CP/M program was offered on Simtel-20 that scanned the program of your choice for disk I/O and flagged it for analysis.   regards, der

Was this a serious posting? Having just laid out $149 for an 850 Interface, I am suspicious. I can believe $25 for maybe the main board or something similar as I have seen parts advertised in magazines for roughly this amount -- but not the whole 850 interface. As far as disk drives go, maybe $75 for an 810, but the 1050 disk drive is still the current model and is going for from anywhere around $160 to $199. Like others who have responded to this posting, I would like to know who and where as I would not mind buying an 850 for $25 or an 1050 for $75. I just question the reality of this. I have seen 800XL's going for $69, Sear's had them for that until they cleared them all out. The local computer stores still are selling them for $99, sometimes on sale for $89.

--Bill--

By the way, should anyone be interested, I B Computers, 1519 S. W. Marlow Ave., Portland, OR 97225, still has 850 Interfaces for sale. I have no interest in nor do I work for I B Computers.

Has anybody out there noted the news about the 65816 16-bit upgrade chip for the 6502?

If what I read was correct, this will be a plug-in replacement for the 6502 which will extend the instruction set to handle a lot of 16-bit operations, sort of a la the 6800 or 8088 families. It is rumored that Apple is considering using this to upgrade their model II series, and it has occurred to me that it would be neat to drop one in my Atari 800XL. If it is truly upward compatible at the machine code level, that would open up a new world of enhanced performance and flexibility, such as (I speculate) 16-bit relative addressing, no more scrounging for zero-page addresses, etc.

Any comments from the truly knowledgeable?

To refresh a 640 by 400 bit screen 70 times per second from memory 16
bits wide requires reading memory 1.12 million times per second. It
takes 4 clock cycles (minimum) for the processor to read a word from
memory. I would assume the same applies to the screen logic, *plus*
the time it takes to get control of the bus before reading, and
relinquish it after reading. With an 8 megahertz clock, the screen
must be slowing down the processor by at least a factor of 2.

Or have I made a mistaken assumption somewhere?

With regard to the argument over whether the amiga can be considered a
business computer:

I think it's largely a question of attitude. One place I have worked at had
an existing stock of CT workstations which were used for minor word
processing, and occaisional use of traditional business products such as
Multiplan. Then a few Macs showed up. These proliferated rapidly when it
was discovered that that they multiplied productivity of graphic design and
project planning spectacularly.

THe problem I see in the marketplace is that, sad to say, the is a great
lack of imagination as far as the use of these machines is concerned. When
the IBM PC came out, people thought of business products as things like
Visicalc, Profitplan, and like things: things that people had always done on
mainframes, and which they now were bringing into their offices. The one
real advance at this stage was the spreadsheet method; other than that, no
one stopped to think what kinds of things they could do. In this respect,
the PC was the perfect business machine; it was merely a scaled-up,
incompatible version of the CP/M machines already in existence, with "IBM"
on the wrapper to make it socially acceptable.

So when the Lisa came along, and then the Mac made it affordable, relatively
few people jumped at the chance to be able to do a lot of radical new
things. Certainly part of the failure had to do with marketing. But I
think that, given the obvious application to a lot of business tasks, the
greater part of the fault lies in the lack of imagination of the business
community.

The 65816 book will soon be published by Brady. The author is David
Eyes. If you really want one badly, give them a call, you might be able to
bum a review copy if it is not yet on the shelves.

Western Design Center did the design. Unfortunately their app-notes
and other documentation are (last I looked) inadequte. The chip, on
the other hand, is very real and very fast.

re: dropping a 65816 into your Atari 800XL in place of the 6502, to

upgrade it to 16 bits: Note that ANTIC (the screen display chip) is also an 8 bitter, so you would have to confine your display RAM to within 64K addresses. That's a real bummer - because one of the real advantages of lots of memory would be to have several alternate screens in memory at once and switch between them for animation, etc. Also, having usable RAM above the display area violates Atari 8-bit software architecture, which always puts the display area at the top of available RAM - the extra memory would not be usable by most 8 bitter programs (but you could make RAM disk(s) out of it).

Then there's the problem that none of the existing memory decoding handles more than 8 bits. Also, you'd have to find a place to put the additional memory chips without destroying the RF shield - a packaging nightmare.

Sounds like an awful lot of work to me, and when you finished up you would still not be able to run ST programs because of instruction set differences between the 65816 and ANTIC and their ST equivalents. Unless you want the experience of tearing apart your 8-bitter and learning something, I think you'd be further ahead to buy a new ST. (Of course, those of us who use our 8 bitters for word processing, game playing and bulletin-board-calling don't really need 16 bits anyway...)

     Dan

>Or have I made a mistaken assumption somewhere?
>
>David Canzi

Yes. Although it takes 4 clocks for the processor to read a word from
memory, that doesn't mean it takes 4+4=8 clocks for both the processor
and the video display circuitry to get a word from memory. If memory
is fast enough, it is possible to run the processor at ALMOST full
speed and insert video display cycles in between processor cycles.

A rough (from memory) diagram of a 68000 memory access:

```
(ns) 0           125           250           375           500
(clock)  |    1    |    2    |    3    |    4    |
     |         |         |         |         |
     | setup address    | start memory     | wait for mem
     | deassert address
     | and control | cycle       | acknowledge | and control
     |
     | signals |         |         | signals |
```

The 68000 only needs access to the RAMS during clocks 2 and 3 (as I have
indicated them above). If hardware was clever enough, and memory
fast enough, you could sneak in a video fetch during cycles 4 and 1.

This is exactly what the ST, Macintosh and Amiga do. They all have fast
memory (250 ns -- ST, 280ns Amiga, ?? Mac) and stick a video (or whatever)
cycle in there with the processor access.

Why did I say "ALMOST full speed"? The 68000 is an asynchronous part
(that is to say, its not synchronized with the bus), but the scheme
I presented above IS synchronous! The arbitration circuitry inserts
wait states until the processor gets synchronized to the bus. So long as
the 68000 executes instructions which take a multiple of 4 clocks, it will
stay synchronized. Unfortunately there are a few instructions which
take 2 (mod 4) clocks, and which cause the hardware to insert wait states
(effectively throwing away 2 clocks).

     "The store is called San Salvage and is located in Nasau county"

Ah ha, Watson, a clue! Well, a little detective work revealed that
there *is* a place called San Salvage, located in Farmingdale, L.I.
They answered their phone (516/249-1818) to tell me that they are closed
on Tuesdays (!). Stay tuned ...

Thanks for the info on San Salvage Co. I did some further checking . .
. . . they are in Farmingdale NY, at 516-249-1818. They DO NOT take
phone or mail orders!! Cash and carry only. They were closed today,
but a woman who answered gave me the previous information. They will
tell you over the phone if they have a particular item in stock and the
price, but only when the store is officially open. If anyone lives in
the Farmingdale area, I would certainly appreciate it if they would buy
an 850 for me and I'll send a money order (or cash) to them. Any
volunteers out there??

For your information, I've gotten responses back from people you have NOT
been able to update their 520ST to 1meg. So far no one has been able to
verify if the mmu has changed or not, in the other peoples machine the
drams had a metal cover (unremovable) on them so you couldn't piggy back
the chips. I would guess that you might be able to replace all the chips
but I don't know.

I put the previous rumor on the net because I felt it was important to
put up a warning flag. I, for one, don't want to spend $1000 on a machine
only to find it can't be upgraded. I fail to see how this falls into the
"silly and irresponsible rumor" category. I hope the rumor is false, but
isn't that why we read this net to find answers to questions we have, and
to pass along some information that might be usefull?

I talked to a local dealer who will be getting some new 520s this week, he
said he'll check it out (he also does upgrades), and I'll report back when
I hear from him.

Hi out there...
I have an Atari 400 (!) which I picked up a while ago real cheap. I was wondering if anyone has any information, pointers to info, etc., about the 850 disk drive, how it electrically hooks up, how it talks to the 400/800 computers, etc. I heard rumors that it talks using RS232 protocol at 19,200 baud. Is this true? I want to try emulating the disk using a Macintosh, so I can use a 6502 cross-compiler I'm writing.
Thank you in advance.

I notice another response to this problem which may or may not be accurate. According to the spec for Gemdos in the developers kit, when a program is loaded into memory, the stack pointer is set to point to the top of the TPA.

This means that the program will use all available memory for its heap space.
To make room for a program to be pexec(), the spec says that you should
reduce your stack/heap space by changing the stack pointer to a more reasonable
offset from the end of the bss and free the memory above the new stack pointer
using mfree(). This makes memory available for the pexec()ed program to use.
I believe this is done in gemstart or gems, but I don't have my documentation
with me so I can't be sure.

How does one open a disk file for reading with TDI Modula-2?

I have tried to get OpenInputFile in the InOut module with
unsuccessful results.

If anyone has this compiler, please let me know how you have
gotten disk files to work.

Here is a question I asked long ago. Maybe some of you that use ST Logo
can answer it.

How can a procedure permanently modify one of its formal parameters?

Is this possible?

Thanks in advance,

A couple weeks back I posted a message asking if the ST, used as a
terminal emulator, could properly handle inverse video, "curses" intense
programs (like maybe rogue), and my favorite editor Emacs. Since I got
a number of messages from people who also wanted to know that info I'll
just summarize the responses here.

First off, "Thanks!" to all the people who took the time and effort to
answer my questions.

I got five messages from people who are using Mark of the Unicorn's
PC/InterComm emulator. It handles all the "features" I was looking for
plus it can handle Kermit, XMODEM, and ASCII file transfers. A common
remark has been "I can't recommend this software enough". Other features
are programmable function keys and an excellent manual.

I also received responses from people using the built-in VT52 emulator
that is "good enough for Emacs and other UNIX work". One thing about
this s/w is that you should use a modified termcap entry (available on
the net).

Thats the only two emulators that people have reported, but at least my
question was answered - the ST is quite usable as a terminal and that
sure makes a great excuse for buying one :-)

My ambition is to be able to read a sequence of integers from a file.

I am able to open the file with OpenInputFile("pentde.txt");

The contents of pentde.txt is several integers, each on its own line:

```
0
1
2
3
2
1
2
3
4
```

3
2
4

My ambition is to be able to read in a sequence of integers from a file.
I am able to open the file with:

```
OpenInputFile("pentde.txt");
```

The contents of pentde.txt is a group of integers, one per line:

5
6
7
5
4
3
2
3
4
5
6
7

When my program runs, every other read doesn't work, and every other read
..... I mean the first, third, fifth, etc reads work, and the
second, fourth, sixth reads don't word (read in a zero).

So what's wrong? If you know how to read in a sequence of integers
from a file, please let me know (sent me a working program).

Thanks in advance,

It is impossible. We here at Ames have a main DECNET (VMS & some RSX),
and a few scattered UNIX systems. They are working on the networking
problems between DECNET & Usenet, but so far no go. BUT....I am
CURRENTLY writing to you from a VMS machine! I do NOT get to a
Usenet node, but am forwarding through the ARPANET (thus get really
frustrated at all this mention of nifty stuff in net.sources......).
If Atari can get a TAC access, or establish one of their VAXen as
an ARPANET node, then they could participate in these discussions
more directly.

ARPANET was recently split into MILNET and another one (I forget the
name...), They would be able to connect into the other one.

I would suggest someone from Atari contacting one of the Universities
which is represented on the ARPANET, and finding out more about this
possibility.

Yes, and that is merely 892 ns cycle time. The memory according to BYTE
is 125 ns cycle time. Plenty of spare time. Controller chips and other
interesting things keep the CPU from occupying the memory for more than
one cycle.

A recent poll has confirmed the impression that interest in Atari
computers is divided according to architecture family, namely the

8-bit and 16-bit families. Accordingly, the list is to be divided. Exactly how this division will effect the individual is described below.

Direct contact with INFO-ATARI@SU-SCORE will change as follows: Two new lists have been created INFO-ATARI8 and INFO-ATARI16. They are both copies of the original INFO-ATARI. Please send a message to INFO-ATARI-REQUEST@SU-SCORE for additions and removals from either list. Presently, INFO-ATARI will point to INFO-ATARI8; eventually it will be removed.

Redistribution of mail conserves net overhead. I assume that the various redistribution sites will follow the same conventions as described above.

There is a mirror between ARPANET/DDN mail as described above and the Usenet news group net.micro.atari. We are working on getting it replaced by net.micro.atari8 and net.micro.atari16.

If there are similar mirrors to other bulletin boards and information systems, their administrators should send mail at once so they can continue to receive messages.

Sincerely,

- Marshall D. Abrams, moderator

IBM and Atari and Apple do not have Jay Miner, I rest my case. IBM or Apple
might be able to do a quick and dirty imitation of the Amiga at a huge
cost, but they won't until they feel the pressure of large Amiga quantities
in their market.

If you have $2000 to spend, ae you going to shop at K-Mart or a computer
store? You might educate yourself first, then go to the Computer store
(why do I have the feeling I will see flames about this?)

As long as Amiga and the ST are so wide apart in price, they will not
compete with eachother - but together they might destroy the Mac.

By the way, (no offense intended) it seems to me that the people who ae
so pro ST like to exercise the left half of their brains while the pro
Amiga people exercise the right half. To the left-half people, monochrome
text in high resolution is appealing. To the right-half people, high-resolution
color, speech, audio, etc. is appealing. To each his own, but as a right

brainer, I have a monochrome hi-res (640x400) AT&T PC to satisfy my left brain, and an Amiga, Commodore 64, and Atari 800 to satisfy my right.

mike schwartz (sorry for the typos, this keyboard sux)

I've just heard an interesting rumor that I hope is false! It seems Atari has switched a chip in the latest 520STs that will not allow the machine to address anything above 512K! And whats worse is that the old chip cannot be bought. This means if you want an ST that can handle a meg or more you have to buy a 1040ST.

I was planning on getting the 520 and upgrading to more memory when my wallet gets fatter. I would guess that a lot of other people have/had the same idea.

Anyone else heard anything to that fact? Also, it seems all the chips are soldered now (even the cpu).

It appears Atari will continue to support the 8 bit line. Information
has just recently gone out to retailers showing that atari is going
to release a new replacement for the 800xl which is the 65XE. In
addition they plan to introduce a boxed system including disk drive,
130XE, monitor and printer. It said to be priced cheaper than the
the C128 with disk drive, at 499.00. Atari still has big plans
for the 8 bit line..

When the atari first came out, I couldn't see paying $160 for an 850 interface
so I hacked the capabilities I needed for printer and modem in software and
used about $5 worth of hardware through the joystick port.
Last week I finally bought the 850 since I couldn't resist the price of only
$25. This place also had 800XL for $69, and Atari disk drives for $75.
(While supply lasted although I believe they are still receiving shipments).
I can't remember the place, but I'm sure similar prices are available at
other "salvage" retail stores.

Summary: This appears to be a commercial program.

I did a dump of the CP/M-80 emulator and found a serial number and a copyright notice from SoftDesign of Munich. That reminded me of an article that appeared in the December, 1985 issue of "In Stride Tech Notes" published by Stride Computers for their customers. The article was:

> You can now run Z80 CP/M programs under Stride's CP/M-68k system using the CPM-Z80 EMULATOR. This product was previously sold by MICROWAVE and is now being distributed by SoftDesign. Herbert Theiss of SoftDesign is now shipping a new "improved" version of the emulator and hopes to release versions for OS-9/68k, AMIGA-DOS, UNIX V and PDOS "real soon now". Contact SoftDesign, Lichtenfelser Str. 80, 8000 Munchen 60 Tel: 089/87955

I think there needs to be some clarification as to whether this program can be given away. It looks to me that it's a commercial program intended for sale.

>The Software could be down-loaded, just like any other bulletin board,
>but the documentation, micro-floppy... could be sent via regular mail
>or picked up at a local "specialty store" in two or three days.
>Of course they could still pick up $1-$2/hour for "just browsing" and
>still be a "Nice Place to Shop".

I think this is a great idea! When new machines come out, computer companies have a hard time getting people to buy them because there is so little software and user support. What if Atari had built in one of those new single-chip 1200 baud modems (additional cost probably < $100) and provided free terminal software and an 800 number or TYMNET access or something so people could exchange public domain software and information about their machines nation-wide. I think this would have helped the 520ST get off to a better start.

I wonder if anyone else has any ideas about this. I know for sure that the net would be an important consideration for me in buying a computer -- I know I can always get answers to common problems, software reviews, etc. for several machines (Mac, PC, Amiga, etc.). I think that people without direct access to Usenet would probably find such information even _more_ valuable.

Everytime I use MicroEmacs or the pseudo shell "command.prg" I am loosing
(of course I dont know whether it was there before) the cursor. It sort of
fishing in the dark trying to edit a file without having a cursor. I would like
to know whether someone knows how to solve this problem before I start digging
through my development pkg. Thanks for any advise leading to the recovery of
this precious part of my ST.

Haven't seen much of Atari rumors lately so here goes:

Is OS-9 going to be available for the 520ST, 1040ST, TT?
     - When?

When will the 1040ST be available in stores?

Anyone know of either Atari or third party hardware coming out soon?
     - 1,2,+ meg memory boards?
     - co-processors (graphic,mathematical,etc. HOW ABOUT MINI LIP ENGINES)

Right. I think even in Germany Atari has sold about 10.000 520ST's in
December. Our hometown dealer sold about 40 pieces and there are over
200 offical dealers in Germany.

In response number 1 to this note I presented a program in FORTH which was followed by the statement "this example helped me decide that I should not be programming in FORTH". The response was a series of near violent messages essentially excommunicating me from the FORTH community. Let me say that the remark I made was meant only as tongue-in-cheek humor and I had no wish to offend anyone by it. Please accept my apologies and rest assured I will not make that mistake again! Now, if some FORTH expert can send me code for the fibonacci number problem which looks readable and runs I will be grateful. (One respondant sent a piece of code which looked readable but contained the string [recursive] which meant there exists some code that I can put in place of [recursive] to get a recursive fibonacci program but that code depends on the particular implementation of FORTH I was using - if anyone knows what this code is for the Dragon FORTH I would be grateful if you send it to me).

P.S. I have been given a copy of Dr. Dobb's Journal which has an article on recursion in FORTH (Feb. 1982, 7, 2, 64) for anyone interested. An example (factorial) goes like this:

```
: THISCODE CURRENT @ @ PFA CFA ; IMMEDIATE
: FAC DUP 2 = IF ELSE DUP 1 - THISCODE LITERAL EXECUTE
                  * ENDIF ;
```

I would be grateful if a FORTH expert would send me mail telling me whether this is well programmed FORTH. Thank you.

Lines: 64

I have just finished reading the January Byte article on the 520ST
and feel that I should correct a few things that are in error.
The article is well written overall but there are some technical and
personal observations that I disagree with.

Firstly, photo 2 on page 87 shows a beautiful picture of the circuit
board of the 520. The area labeled "RAM address decoding" is actually
the data path switch controlled by the custom MMU. The two 74LS244s
control the data comming from the CPU to the RAM's and the 74LS373s
latch the data from the RAM's onto the databus. RAM address decoding
consists of the RAS and CAS lines from the MMU, when you only have
16 bits and 16 256K chips you only need one select line to make up 512K...

  Now I move on to more grey areas of contention, on page 99 we have the
following:

> "And, to move a a file out of a folder matters are further complicated by the fact that the folder opens to take over the window from which it derived. You would first have to move the file to a different disk, delete the original file from the folder, then copy the file back to the original disk but not within the same folder, and then delete the first copy you made. It sounds difficult because it is."

This is a possible way to perform this operation but it is by far the
worst. If I had this problem I would solve it in the following manner
on a single drive system.

a) Enter the folder or sub-folder that the file was in.
b) Reopen the disk by selecting the A Icon.
c) Enter the folder I wish to place the file in.
d) Drag the selected file to the new folder (to copy the file).
e) Delete the first file.

The only time a second disk is needed is when the disk is limited in space
and the file is large at that point I would.

a) Copy disk A to B
b) Delete the file from the folder.
c) Copy the file from B to A placing it in the proper folder.

Lastly let me take a pot shot at the software issue on page 100.

The ST arrives with Language Disk, TOS system Disk, First Word,
& DB One. Very few systems come with a Database manager, a visual word
processor, a basic and a logo (mind you the last two are not very
usefull for my applications but they are there in a pinch). For the
above list of software on a Blue machine (no names meantioned) I can see
a rather large dent being put in the pocketbook.

The local Atari dealer has been very helpful in getting any of the public domain
programs to it's customers i.e. Kermit, Neo, STW and the rest. They have taken
an active interest in the ST and although they are not technically oriented
they have not tried to "snow" any of the people here at the university.

My last little rambling is the ongoing discussion between the amiga, mac
and st users. Please stop!! The best thing that can be done is to
concentrate effort on developing the respective machines and quit
flogging a dead issue. I read something once about East is East and West is
West and never the twain shall meet. This discussion is a clear illustration
of this idiom.

Suggestion for people who write terminal emulators: either include in
your documentation a termcap entry for your emulator, or better yet,
have a command to send the termcap entry to the host.

Subject: Re: 850 wanted
In-reply-to: your article <8601211538.AA18979@winkin>

I am using an Epson RX-80 off my Atari 800 and it works *beautifully*.
I don't yet have a printer driver program for the RX-80, so I must
insert escape codes directly into my Atariwriter text files to get
stuff like expanded, compressed, italics, boldface, etc. Some of the
Atariwriter control-[letter] commands do work, such as paragraph,
center, flush right, etc. I bought my printer for $239 from 47th
Street Computers in NYC (the *best* price I could find anywhere!),
and bought my interface cable for around $50 from J&R Records & Tapes
(who also sell computers, etc.) also in NYC. I do not have an Atari
850 interface, and don't think I need one. My peripherals include
a disk drive and a printer. When I want to load or save from my
Atari 410 tape cartridge machine, I just unplug the printer from the
disk drive and plug in the 410 recorder. The interface cable I
mentioned was made by some outfit in the Northwest (Infocom? Infobits?
Microbits? something like that...it's home and I can't recall).

A CPM 68K program has all the memory allocated to it, so there is none
left when you try to do a Pexec(). I suspect you have used gems.o, rather
than gemstart.o (if you have the ISV development system), as the latter
reallocates memory for you. Alternatively, use the Mshrink() command.

Well, first off, I think all the 8-bitters have a built in modulator. But

assuming yours is down, they are easy to buy. I think Radio Shack has them
for $10 or so. Also computer stores. Just plug in the composite video output.
They probably need a battery or something, too.

Jim Henry's comments on marketing are well taken. However, Jim, how
dare you be rational in this news group and almost give me a heart
attack?

Here are two additional comments on marketing and business. First, if
you have a successful product, you should sell it hard and get everything
you can out of it. Following this principle, Atari is re-introducing the
7800 game product and pushing 2600's again. The game machines accounted
for a large part of Atari's revenues last year. And for 8-bitters
(and I am one, too), this principle guarantees the continued support of
the 8-bit line.

My second comment has to do with business in general -- business is a
rough game even when played within the bounds of good taste and proper
acceptable ethics. If you aren't willing to play tough, don't get in
the game. In my experience, I've found that most "mom and pop" computer
stores cannot (will not) get into or withstand the "business is war"
mindset. For example, compare the personality, outlook and value
system of your average technical guy who has risen (sunk) to VP of
engineering versus an executive, money man VP. It's pretty clear
who eats granola and who eats ground glass (raw bits????) for breakfast.
Personally, I'm holding out for senior scientist which really says
something about MY personality :-)

Finally, for Amiga vs. ST'ers, toys vs. real's, etc., why dont cha all

fade away. I'm havin' too much fun with my box.

There has been a lot of requests for converting RGB signals to composite
and vice versa, with RF, and so on. The book "Applied Concepts in
Microcomputer Graphics" by Bruce A. Artwick (Prentice Hall)
has a whole chapter dedicated to mucking around with display generation
hardware. In particular, on page 93 it gives two diagrammes for implementing
RGB to colour conversion for standard and simplified computer graphics
applications.

This book is available in most book shops with a "computer reference" section,
and through many computer book clubs. I don't know the publisher's price,
but if you belong to one of these book clubs, or about to join, you may
get it for a few bucks. (I got it for less than $6).

I hope this is of some use.

I know that this is group is for ATARI relates subjects. Ok, fine,
what about the old 8-bit XL series? All (mostly) that I ever see
in this column is news, questions and advise about the ST series.

Some of us out here in netland are poor starving programmers, students,
etc. and can`t afford $1000.00+ for a PC.  Also even though you can`t
run UNIX or some of the more complicated routines on the XL series
(400, 600, 800, etc.) my 800XL and I get along just fine and have a
great time in the evenings. There are many great games for the XLs
as well as lots of useful business, learning, and other types of
programs floating around out there.

Lets have more programs, news, notes, and comments on the XL series.

Hank (The Shadow) Robertson.

Someone mentioned that they have already converted a number of C sources
to Action!. Are any of these programs useful? Would a general posting
(or an upload to the info-atari archives) be appropriate? Does ANYONE
have any interesting/useful 8-bit software that is PD distributable?

Yes, Tramiel's group is in charge of the AtariSoft division now. However,
there will probably be some delay before you see your favorite Atari games
converted to the 520ST, since according to Richard Frick, Atari has nobody
in their organization right now who is able to program on the 520ST.

Ed Friedman

P.S. I would appreciate hearing from any of you developers who feel they have
'mastered' programming on the 520ST.

Well, has anybody out there in net-land an instruction, how I can
make my 520ST hold the time, even when I switch it off. I think I have
heard sometimes ago in the net, that someone has battery buffered the
microprocessor in the keyboard, but I'm not shure about this. So if
there are any hints, please mail them to

Having heard little factual info from what was going on at Atari, I gave a call to Richard Freck, the person at Atari responsible for St development. I was lucky to reach him as he just got out of a meeting, and I pressed him for answers to a number of questions I and others have had regarding Atari products, plans, etc. The following is what I can reconstruct from my notes and (sometimes rather poor memory):

1) There is no GEM Draw coming. They are still awaiting GEM paint.

2) Those who read the last issue of Infoworld probably saw an article regarding a new, less buggy developers kit, that some developers claimed they had to have to do development. The claim was made that DRI was just letting some copies out. Richard didn't have any info on the new software and gave little credibility to the Infoworld article.

3) It will still be about 30 days before TOS in ROM is available to the general public via their Atari dealer. HOWEVER, if you are a developer (and have sent in your non-disclosure agreement), you can get your ROMs right now by sending in a check for $25 to the attention of Richard Frick, Atari Corp., 1196 Borregas Ave., Sunneyvale, CA 94086.

4) The 1040ST should be coming out soon (they are in the warehouse), and will come with a built-in double-sided drive and built-in power supply.

5) Before Christmas there was talk of a number of Atari video games that were to be available on the ST, such as Missle Command.

This didn't happen, but the project was not canceled and Richard hopes they will come soon.

6) I recently heard that Atari would be shipping a copy of First Word and DB Master with every ST they sell, like ST Basic and ST Logo. This is NOT true, according to Richard. When pressed, he said that some stores included this software with the ST at Christmas as a sales promotion. I said I hadn't heard of this, and he said it was up to the stores to mention this. Anyway, he says it is a violation of copyright law to freely distribute this software, as it is to distribute ST Basic.

7) The "official" policy from Atari re the 1 meg upgrade is that it shouldn't be done. Atari will not repair a system sent to them if the update has been done unless it has been done at an authorized service center. When I asked about installing the ROMs, he said they too should only be done at an authorized service center.

8) I'd been hearing various reports over the past few months on whether the hard disk drive would be only 10 Mb, only 20 Mb, or both. Richard said there would be a 20 Mb and a 30 Mb version available, both around the mid-March time frame.

9) I mentioned that I had been using ST Basic for a while not, and uncovered several problems with the documentation and software, and would an updated version be coming out. He said a new version was due out in mid-March, but had no idea on how it was going to be distributed.

10) While the TT is not yet an announced product, I did say that I had heard a rumor that the CPU was to be the 68020 instead of the National 32 bit chip, 32332. The only comment he had was that the 68020's were not yet readily available.

11) I noted that I had not gotten my Atari newsmagazine (the Atari Explorer?) in many months. For that question he referred me to Neil Harris (408) 745-4394.

12) I mentioned that a lot of rumors and comments on Atari fly around on the USENET and Arpanet networks, and was he aware of these networks. He didn't know of them, but did express an interest in them. I got the impression that he would subscribe if it were possible (is it?).

That exhaused my list, and the poor guy was probably glad to get off the hook, but I did say I would pass this info along to the Atari user groups I belong to, so I believe his time was well spent. I've tried to present the above info as "straight" as possible, but if any one has serious questions they can call Richard Freck directly, at (408) 745-4926.

>Has anybody successfully ported any of the Amiga code over to the ST?
>Someone ported some of it to their CoCo/OS-9 system (see net.micro.6809).

Someone (sorry, I don't remember who) recently posted microEmacs to
net.micro.atari. The source came from net.micro.amiga. Not to rub salt
into open wounds (at least not too much, anyway :-)), but the argument
that "the source is too machine specific to be of value to others" is
just alot of hand-waving. Sure, most *any* porting requires some amount
of rework ... hell, even to go from AmigaDOS V1.0 to V1.1 requires some
changes. And granted that a straight across port may not take advantage
of unique hardware, and some functionallity may be lost from the original,
but it provides a place to start working on the next revision ... isn't
there something about "standing on the shoulders of those who have gone on
before me" (or does that only apply to physicists)?

Sorry to ramble on so ... I just get so annoyed when I see something
posted that *might* be interesting to look at, and then on the 2nd or
3rd screen I see "requires BinHex 4.0", or some such drivel! Grrrrrr!!!

Anyway, thanks to whomever posted XLISP to net.micro.atari ... I hope to get it up on my Amiga shortly ... and then I may try to move it over to my MS-DOS machine (tho the C compiler I have there is a little "weak").

/kim

Have you seen the JS&A ad for the ST? It's on the first page of the March '86 Playboy. If I were you, ST owners, I'd be worried. JS&A specializes in selling other companies' failed products with mucho hype. This ad sure fits the mold.

I haven't been able to verify the rumor that the new ST's can't address more than 512K of memory, but this sort of shenigans is typical of Atari. If anybody remembers the final blowout 400's from the old Atari, they had a sabotaged ANTIC chip that couldn't address more than 16K. Fortunately, I had a source of good ANTIC's so I was able to replace the bogus ANTIC.

I am really getting sick of the childish messages on this list that make fun of serious concerns related to the ST's marketing. It is ridiculous to talk about $400 Crays. Seymour Cray only makes multi-million dollar machines, and it costs him millions of dollars (presumably less than what he sells them for) to make each one.

>in their market.
>
Are you claiming Jay Miner is the only competent engineer in the computer
biz? If so, I think you are resting more than your case! :-)

I was not suggesting that IBM or Apple would do a quick and dirty Amiga
imitation if the Amiga starts to hurt their sales. I was suggesting
that they already are working on machines that are as state of the
art as Amiga.

Take the case of IBM. They (at least this is what I have heard, it
may be totally wrong) spend lots of money on keeping up with the
leading edge of technology. For example, IBM did one of the very
early RISC machines, yet it was only this week that they announced
a RISC based product. Similarly, it is almost certain that they
already have all the technology to do an Amiga class machine. To
actually market such a machine would not be a quick and dirty job,
it would simply be a matter of putting some stuff they already have
in one box and selling it.

Heck, even Mattel was close to having an Amiga type computer before they
got out of computers (the machine that would have come after the
Intellevision III was going to be 68k based, and have graphics
and sound capabilities similar to those of the Amiga).

>If you have $2000 to spend, ae you going to shop at K-Mart or a computer
>store? You might educate yourself first, then go to the Computer store
>(why do I have the feeling I will see flames about this?)
>
I would allocated about $100 of the $2000 to go to the local magazine
shop, and get a lot of computer magazines. If I found a machine that
met my needs, and sold for a lot less than the other machines that
meet my needs, I would start to look for it.

It might not occur to me to go to K-Mart and look for it, so I might end
up purchasing the expensive machine from a computer store. But if I
became aware of the K-Mart machine, I would go and buy it there. I see
no reason to become stupid just because I have $1900 in my pocket :-).

Re: "monitor/front panel emulator" - You might look into the monitor
called Omnimon available from CDY Consulting, Richardson TX.   The phone
number there is (214) 235-2146. The chap who will likely answer the phone is
David Young, and he can tell you what his Omnimon will do or send you
literature. I just bought this and a couple of other nifty things from him,
but have been out of town a lot and haven't gotten it up and running yet.

>this precious part of my ST.

This is probably a common problem, so I'm posting the solution rather than responding by mail. There are two basic types of applications, GEM and TOS. The TOS applications can be divided into TOS and TOS-TAKES-PARAMETERS. By default, files ending in .PRG, .TOS, and .TTP are GEM, TOS, and TOS-TAKES-PARAMETERS applications respectively. The only difference between TOS and TTP is you get a chance to enter command line options when starting a TTP application. This application type can be overridden using the Install Application menu item. [Don't forget to save the desktop after doing this unless you want it to go away the next time you boot]

What does this have to do with your problem? GEM applications use a mouse cursor and TOS applications use a standard terminal type cursor. To get the standard cursor, you have to specify that this is a TOS application. So, if you change MicroEmacs to me.ttp (so you can put a file name on the command line), or install it as a TTP application, you'll have a proper cursor when it runs.

     This one is easy, once you figure it out. Don't call the file
.prg! Use .ttp or .tos. When you rename it to .tos, the cursor
stays. (This is independent of the set options menu - you must rename
the file). As far as I know, this is not documented anywhere, but I
just accidentally discovered this.

Agreed wholehardedly! While the XL/XE series can't "run" UNIX, with the Chameleon software program from Antic, you can use any Atari computer to interface with a UNIX/UNIX clone system. That is how I get on line with the net from home. 130XE > tekigm2 > net.world. Chameleon converts your Atari to a VT52 (or VT52XL) terminal, the termcap is listed in the documentation furnished on the disk for Chameleon.

--Bill--

This is also an ST question. While we are on the subject of cursors, does anyone know how to get the cursor to stay on all the time. Having the cursor on the screen half the time is alot better than not at all but it still is annoying in EMACS. Thanks.

Author:burman@brl.arpa

Request:

I am interested in purchasing a 520ST or 1020ST (if they are available
in the not tooooo distant future) while I am visiting the US. To date I
am still, however, debating whether it will be with a monochrome or
colour monitor, but whichever way I decide to go I can forsee problems.
At the end of my stay I will be returning to Australia and have to plug
into the local 240 VAC 60 Hz supply. I can easily use a step-up
transformer for the CPU-keyboard and Disk , only one more transformer to
add to the rats nest under the computer table. What has me worried
though is the question of whether the monitor uses line frequency for
the screen generation for either of these types of monitor.

Since I will be passing through Europe on the way back from the US I could
of course buy a machine over there for PAL/240 VAC/60 Hz system. Is there
any information available on prices in Europe for these machines?. I
would be interested to hear from anyone who could help me.

Thanks in advance for any assistance. N.M. Burman burman@brl.arpa

Atari says on the phone (if you can get through) to send them a
cashier's check or money order for the ST Developer KIT. Address is
Atari Corp, Attn.: Richard I. Frick, 1196 Borregas Avenue, Sunnyvale,
CA 94086. At least one "full-service" computer store which carries
the ST had no idea of the details, and could only say "Call Atari."
They did know the cost, as has been mentioned here, $300. Their
knowledge of kit contents was minimal. On the phone Atari quoted 4000
as the number of pages of documentation included.

A couple of days ago someone mentioned that they had bought an atari 850
interface for $25.00.

Could they please come forward with the name/address/phone number of the
place they made this purchase? Several other people on the net are interested
in buying a copy of this interface!!!

Thanks 10^6

There is a lot of debate on whether either of these machine is a
"business computer".

Perhaps a new definition of "Business, Personal, and Personal Business"
computers is needed.

A VAX 11/750 an ST, and Amiga both run at nearly the same speed (Integer
math only). For the "big 5" applications, (word processing,
planning/budgeting, small databases..., reports and documents that are
published via office-copier) all of these machines will do about as well.

The VAX is a business machine in the sense that it will do large data-bases
that wouldn't be needed for "personal use". Updating a 2 gigabyte file
hierarchy and having it available instantly to 100 users is not a
task I would assign to an Amiga (it doesn't have 40-100 terminal ports).

There are machines that do that well (such as a CCI 5/32, Altos, and maybe even a PC-AT) that were designed to handle that kind of heavy usage.

On the other hand, try using nroff to send presentation quality graphics to a daisy wheel printer on a 4.2 system, and compare that to what you can do with an ST or Amiga in about 1 hour with one of those Draw/Paint programs. You might get a reasonable looking table after two or three hours of hacking at a 'tbl|nroff' document, but none of the really good font and shading stuff you'd get with an ST/Amiga and an OKI printer.

As far as the "Toy Computer" syndrome, remember that the first 2600 (the only true toy) and games were written by a man who wrote missle simulations for the department of defence. Even the "Star Raiders" style games show the potential for real-time simulations. Carl Peterson (Accelerated Schools, Denver Co.) pointed out that for education, simulations were superior to "drill and practice" or "text tutorials". Some schools use variations of the "Hammerobi" game as a way of teaching economic principles.

Home/Personal computers will have to provide "entertaining education" to fuel a strong "Third Wave" of computers. Considering the "First Wave" was the Timex/Sinclair and the second was the Commodore-64, the "Third Wave" could be worth several million units. Of course, C-64 owners discovered that their "game machine" could also be a useful "Tool" in such persuits as paying the family bills, mailing "form letters" to all the "Children, Grandchildren, Uncles, and Cousins".

The Atari/Amiga has the ability to become a "cottage machine". If a person wants to stay at home and update data-bases, type resume's, or print form letters, they can do it with these new machines as well as the person with the VT100 sitting at the office desk.

The real key for the "Personal Business" computer will be the ability to make efficient use of the resources of the "Business" computer such as the VAX.

Some examples:

Given a relational data base such as those produced by lorder, cflow pass 1, join or any other "parent child" relationship, draw and organizational chart of it in somthing like a yourdon structure chart.

Produce a "3 dimensional" chart similar to the above, but "mouse-clicking" let's you see the "children" and "mouse-left button" lets you see the description.

An old article in kilobaud (1976) described a 3-d datebase that was accessed using two joysticks (could be mice or track-balls today) the viewer could see both the top and front (isometric view) of the data-base and access anything in it by positioning on the three co-ordinates. This is as opposed to the 2 d windows.

Produce a system like the above for accessing/navigating a unix hierarchy.

Devlope peer-peer communications protocols where the operating system
of the "Host" is an integral part of the "Personal Computer". For
example when you want to "open" a file that lives on a VAX, let the VAX
traverse hierarchies, read indexes... and manage a "virtual path"
between the open file and the PC. This is an optional feature of OS-9
68K and could be the strongest case yet for adopting it. OS-9 also supports
a full, standard graphics 'driver'.

The IBM-PC can't do this because so many of the
desk accessories, copy-protected applications and other "Micky Mouse"
programming practices for that machine try to access "BIOS" routines
directly to the "Physical Device".

Also, allow bi-directional "piping" between the two processors to
allow remote execution of such common tools as filters... on the
the "Unix" machine with input and/or output provided by the PC.

Develope a "graphic interchange language" that could be read like
a text file to enable things like print-spoolers, choice of editors,
and conversion of text data to graphic data. Alternatively, develope
a generic graphics interchange format that would allow the same flexability
with graphics that unix text files provide for the unix tools.

Some things I would like to see after using MAC programs:

graphic versions of 'grep', 'awk', and 'sed' as well as the ability
to search for say 'a box containing the words "application services" in
a 'project' document and draw a line to, or be positioned at that point.

a graphic version of m4 so one could produce 100 boxes containing
(1 line per box) the lines of text, centered in the smallest possible
square, or in squares of a specific size. The output should be usable
by either the (Machine equivelant to) Paint, Draw, Project, Draft, or Cad
editors.

the equivilent of a 'join' capability where supplementary text can be
joined (added into, or opened from) a box on the graphic 'picture' document.
also the ability to 'join' by drawing a line from one box to another
based on the lable contained within the box.

A 'format standards' document in each applications manual, to allow
conversion from one applications format to another.

the equivilent of a 'diff' capability to allow using features of
two editors, and be able to convert, add, remove those features
added by the new editor. For example, after using the 'project'
editor, and using the shading and 'spray can' features of the paint
editor, the 'project editor' can't be used again. If the original document
is manipulated, the 'paint stuff' has to be done all over.

This is the right way to get just about any answers. There have been a number of
times that questions I had about the ST were easily answered just by being
persistent about calling Atari and getting shuffled around. A reasonably
intelligent exec would rarely just blow off questions if they are intelligent
and (obviously) if the answers are not embarrassing or supposed to be kept
secret. And in fact, Atari has never been secretive, just not overly enthusiatic
about getting details out. If more people would just ask Atari there would be
more info in the group and fewer questions... If we all pitch in maybe we
could get Atari on the net. Is there anyone who has any ideas about this?

Reply-To: pm@cwruecmp.UUCP (Prabhaker Mateti)
Organization: CWRU Dept. Computer Eng., Cleveland, OH
Lines: 35
Keywords: CP/M 520ST
Summary:

Here is a method for transferring files from TOS to CP/M-emulator's disk.
It is painful, but using this technique I moved several files including
PIP, STAT, DDT, BDS C compiler, etc. I own all of these on an Osborne-1
that I rarely use now. This is being posted in a 'good spirit.' Don't
send me or this group any flames on the legality of this.

Enter CP/M emulator. Insert a TOS-formatted disk. This should contain no
files (either TOS or CP/M). Now issue the CP/M command

save 32 junk.ddd

which saves 32 'pages' of CP/M core image as file junk.ddd. This
ofcourse contains garbage, but never mind that. Now exit CP/M.
Write a program to run on TOS to read a file (from a TOS disk) and
wait until you change
the disk to the above CP/M disk (with the junk.ddd file), and write
the file out onto consecutive sectors whose logical numbers
begin at 26. (Because we saved 32 pages (== 8k), make sure the file
you are transferring is <= 8k. If you want to transfer larger files, change
the 32 to whatever.) A SSDD TOS disk has 9 sectors (numbered 1 to 9)
on each track (numbered 0 upwards). So logical sector number 26 (say, s) is
track 2 (== s/9) phys sector 9 (== (s modulo 9) + 1). Each sector holds
512 bytes.

I suggest that you transfer either a vanilla MODEM7.COM or PIP.COM this
way. Now re-enter CP/M emulator, do a 'ren pip.com=junk.ddd' (assuming you
transferred PIP). Type 'pip' and you should see the '*' as the prompt.
Once PIP is working, you can copy files in a number of ways. The CP/M disk
with files can be disk-copied with TOS (e.g. COPYDISK.PRG).

You are not the first, who wants clearification. I got in the last days
some mail and I think I must say something to this here in the net:

1. The CP/M-Z80-Emulator was originally copyrighted by SoftDesign in Munich.
2. The University of Dortmund got as offical developer the CP/M-80-Emulator
   like all German Atari dealers with a letter in which Atari Germany (in
   Raunheim at Frankfurt/Main, near the US-Airbase in Europe) told developers
   and dealers that this emulator can be distributed FREE (!!!!) to all ST
   end users. We also saw this copyright notice and in order to verify I called
   Dr. Riedl, the German Software Support Manager of Atari, and asked him,
   whether we can send the emulator via Usenet to USA. He answered me, that
   they have the distribution right for the emulator all over the world and
   that we can mail this piece of software. That's all.
3. I think Atari Germany has bought the copyrights and distribution rights
   from the Munich firm. Even I hope so. If not, I think, Atari would have
   got very much trouble in the meantime, because we received the emulator
   in December 85 (including the letter, that it can be distributed free).

I hope this will help. If not: Sorry, that's all I know.

    By simply changing the file name extension to ".TOS", the cursor will be retained. This is true for any executable such as Micro-Emacs, Command.prg, etc.

Summary: Got you, arf, arf!

...for Atari 520 ST. I discovered this program (grapesto.prg) on one of a set of disks with various cute demo programs, and when I tried it out it destroyed the disk. It identifies itself as "Grape Stomper", displays a diagram and several on-screen buttons. The "info" button displays a blurb to the effect that this is freeware, send us what you think it's worth, and names two (probably fictitious) authors.

When you press the start button, it appears to destroy disks in reverse order, disk A last, ie. it goes for the hard disk first if you have one. (Fortunately, all I was working with was one floppy, and all that was destroyed is replaceable.)

Anyone out there used the gemdos Pexec command? It supposedly allows one
to call other programs from a main program. I've tried everything I could
think of to get it to work, but I've had no luck. It keeps returning error
code -39. According to the gemdos manual, this indicates not enough memory.
But I know I've got enough memory, becase the main program is about ten
lines long and the sub-program is about five lines long and I have a one-
megabyte machine! This is terribly frustrating! If anyone can offer any
suggestions or perhaps a solution, I will greatly appreciate it.

I would like to get a correct termcap for the VT52 emulator in the ST.
I don't mind trying to generate it myself, but I have no idea what
characters the mainframe needs to send to the ST (except the
insert/delete line that was posted earlier).

It seems like the termcap for the actual VT52 isn't quite correct.

Now for the availability question:
How long has it taken YOU to get the Development Kit, and how exactly
did you go about it?

Please mail the answers to me, thanx.

SUMMARY:
The Hippo RAMdisk has a nice GEM-driven menu/installation program used to create RAMdisks from 1k to 4 MegaBytes. However with TOS in RAM, an active workbench (open windows, reconfigured Control Panel), let alone an application program running, one quickly finds the practical limit to the RAMdisk is rather small for a "disk".

Description:

A RAMdisk is created by running the program and chosing options from the menu. The program uses a GEM environment so options are chosen by selecting the desired pop down menu with the mouse. With a RAMdisk installed, a new disk drive token appears on the GEM desk top labeled "H". This is the RAMdisk and it is accessed just as any other disk in GEM.

The installation program creates 3 files which are used at boot-up time to create a RAMdisk. I have found that I can make RAMdisks of various sizes saving these 3 files in sub directorys [Folders] on the boot-up disk. To change the RAMdisk's size I only need copy these files to the main directory and reboot the system.

RAMdisk size limitations:

With GEM loaded the largest RAM disk that can be created on a 512k ST is only 72k. Attempts at making larger size RAMdisks either crash the RAMdisk installation program or crash the ST upon booting up. You may find that other programs will not run with too large a disk. ST WRITER runs OK with a 72k RAMdisk installed, but only 16K of space is available for your text. MEGAROIDS and BOING will not run with an installed RAMdisk larger than 2k bytes! (This may not be the case with an expanded ST or TOS in ROM.

With my single drive and a RAMdisk and I am able to copy numerous files to and fro avoiding the usual 4-swaps-per-file. But without more RAM, I don't think it will be big enough for things like compile-linking without the disk swaps of a single drive system. Without memory-hungry GEM there may be enough room, but I do not know whether the RAMdisk will run apart from GEM. And the largest RAMdisk that can be created using the GEM-driven menu is 72K! I guess I just have to invest $50 for a 1-Meg upgrade or wait for the ROMs.

Little Help from Documentation:

It is a good thing that the GEM menu of the installation program is so intuitive, because programming instructions are minimal at best. No "hard-copy" instructions come with the disk. The only instructions is from a one page (<=66lines) direction sheet (I don't

dare call it a manual!). This direction sheet is read by selecting a "help" menu from the RAM disk program and clicking the mouse on the only help option called "show manual". The directions are then printed on your monitor screen.

These instructions say to adjust the size of the RAMdisk until you have no problems running other programs. If the RAMdisk is too large, then trying to run a program will result in an immediate return to GEM (if you're lucky), "mushrooms" appearing and/or a crashed ST (if your are not so lucky.

Other than this there are NO instructions. I guess I have grown accustom to the "idiot proof" 400 page manuals (ah-la WordStar and other MSDOS/CMP products). These big manuals usually start off by telling what a smart person you are for buying this wonderful product, and that you will now become more organized, spell correctly, be admired by friends and colleagues, and have fewer cavities. It then will cover in minute detail how to make a backup copy of your program using the <drum roll please> OPERATING SYSTEM commands like "copy". It then takes you step by step into running the program..."now place disk into dive A:"...etc. I certainly am no worse for the wear by not having another 3-inch manual lying around. But what of someone who does not know a byte from a snack? Well, perhaps Hippo thought that such a person would not know (or care) what a RAMdisk is, much less want to use one.

I am working in a Physics-related research lab. Therefore, my view of computer is based on the capabilities of data manipulation, real time graphic representation of the incoming data. AND how easy it is to get the information about the machine's hardware and bios (dos also)---important when doing

custom interfacing.
After seeing the recent flame on the comparison between Atari 520ST and
Amiga, I am wondering the following things:
(1) Is there a bus expansion 'slot' to add a (say) IEEE488 interface ?
    (i.e. what is the bus structure in these machines ? Is it expandable?)
(2) Is it possible to add a so called math coprocessor chip for 68000 if
    one is available ? I don't think the 68000 alone can beat the 8088 and
    8087 (OR 80286/80287) combination in number crunching .
(3) Is the technical reference manual complete ? any bios listing ?
    dos information (low level) ?

For me, if it is difficult to do some custom interfacing or if it needs
overnight to get a theorectical curve ... then it is not worth (either
$400 or $1300) to replace my current machine (IBM-PC).

> ... Amiga is setting a standard.

Where?

I am fanatically opposed to the misuse of the english language. Please
look up "standard" in your dictionary. What is "standard" about the
Amiga, and what standards has it generated?

If you don't have any evidence, then you are wasting our time.

The Amiga vs. the ST debate can go on without me. It is a waste; what
possible difference can it make? It will have no outcome -- there are
two (possibly three) camps shouting at each other from their trenches.

Suggestions for new topics:

- Broadcast bugs! This will help other developers, and (yes)
  people from Atari /do/ read this.

- If you have hacky utilities, bits of hard-won magic code, or
  special techniques, then post them!

o What would you like to change in the ST? What parts of the machine most mystify you? What are you doing or developing with your ST, or (if you don't own one) what are your reasons for buying or not buying one?

o Heard of any great products recently?

o Gossip/rumor: what's /really/ going on at Atari, anyway...?

A project I am leading wrote 12000 lines of C in about four months on
a VAX running Berkeley 4.2 UNIX. Then we tried to port it to the IBM AT
running PC-DOS and Microsoft C V3.0. Six hours after we started moving

the source over, it ran. Perfectly. Is this portable?

> Is it worth it for portability to have
> programs that run at half the speed (or less) than the computer is
> capable of (or will it matter if they make computers go fast enough)?

Ask all those companies that right now are wishing they could move their
8088 assembler language programs over to the Atari.

> Should it matter that a language called Action (similar to BASM) on a
> toy Atari 800 can compile a megabyte of source code (a little overstated)

>

One of the reasons that the Atari ST uses GEM is because GEM provides
a consistent interface for application programs, and GEM works on the
IBM PC family as well.

> I have not been trying to flame 'C', which is a Ratfor for PDP-11 assembler
> language, so please nobody take this as a personal attack against some

>

What we need are 'C' compilers that WORK! Microsoft V3.0 is real good.
It is the only C compiler for the PC family I have seen that is trustworthy
and useable. I just wish it was available for the Atari.

> I shudder to think of a highly structured 'C' program spending the
> majority of its time pushing and poping registers, passing arguments,
> and returning a whole byte (or word or more) for a true/false condition.

Sounds like you are objecting to structured design. Maybe building
video games structured design isn't important because video games, while
complicated, aren't subject to the levels of maintenance and enhancement
that other products are. (If it doesn't do what you expected when you
move the joystick, you can just define a new "rule" for the game).

Does anyone know what is holding up GEM Write for the Atari 520ST?
It's been available for months for the PC, and since GEM Write is
written in Pascal and uses GEM, it _ought_ to be available for the
Atari.

Has anyone found a word processor that's actually available for the
Atari that uses GEM to produce a Microsoft Word or MacWrite style
word processor?

In case you wanted to know: the vt52 emulator (desk accessory)
does have add line/delete line capabilities. I believe ESC-M
and ESC-L are the sequences necessary... try it out. If you
want, I can mail you a termcap that makes use of these
capabilities.

I'm considering buying a terminal for home use, but I also have an ST in
my plans too. My question is: are the vt100 emulators for the ST good
enough to do a lot of work on? Do they properly handle inverse video,
"curses" curser movement (I'll be working on Unix systems), and how
effective are they when using Emacs? Do they have file transfer capability
or at least buffer capture?

I'll be using a 1200 baud modem, will there be much difference in speed
between a terminal and the emulators at that speed?

I'd appreciate hearing your comments on the different emulators that are
out.

Thanks in advance,
--

     A friend of mine thinks there is a handler missing from the
old Atari-800 operating system. You should look for an article in
An old issue of Antic magazine, he is not sure which one. It is
an issue between July and October 1985.
                                        Good Luck!

Logic:
Small computers are toys.
All computers are getting smaller.
Thus, all computers will become toys.

Solution:
Bring back the vaccuum tubes.

I need help from someone in the LA area. Cal State @ Northridge is
sponsoring the 1986 North American Computer Othello Championship
Tournament Feb 15-16. I want to enter a program I wrote on my Atari 800,
but there is a problem. My program is written on a double-density disk
under OS/A+. My drive is in the hospital so I can't convert it to an
Atari DOS format. What I need is a volunteer with OS/A+ to take his/her
computer to the tourney and run my program by proxy. Here's what's in it
for you:

 1. a free copy of my Othello program which is (near) commercial quality
 2. the excitement of the tournament itself
 3. a warm feeling in your heart for doing a good deed.

If there are any takers, please send reply to me directly
 godden.gmr@csnet-relay
and I'll contact you for details and arrangements. THANKS.

-Kurt Godden

P.S. If any of you would like more info about the tournament, you can
      contact the organizers: Marc Furon 1gtlmkf@calstate.bitnet
                     and   Brian Swift agtlbjs@calstate.bitnet

I called ATARI within the last several weeks on the 745-2000 number and
had no trouble getting in. What I did though was call it at 7:30 A.M.
Denver time which was 6:30 A.M. California time. But someone did
answer and my request was handled correctly.

   A few days ago someone talked about how similar ACTION was to
'C' and how easy it would be to write a program to translate from
one language to the other. I had the same idea. It would be
real handy to be able to translate between the two. Before I get
all ambitious and waste lots of time, HAS ANYBODY ALREADY DONE THIS?
Has anybody thought seriously about it and come up with any real
stumbling blocks? How about things that are possible but tricky?

   If someone has done this, write me.

   If people have suggestions, I welcome them all,

Warren Long

I would like information, gossip, rumors, and speculation on how long
ATARI will continue to make, market, and support the 8-bit line.
Also, how large a change in the operating system was made from the 800 (old)
machines to the 130XE machines (references would be nice).
 I've not heard any rumors one way or another but have not seen any ads
for the 130XE or the peripherals by ATARI-I may just have missed them but
it seems that with all the ST and TT talk, us poor 8-bitters may be left
out.
  Lastly, would it be feasible to not split the two groups but to put the
mail in digest form where you send out muliple volumes with some general
info., some 8-bit specific, and some ST-TT specific mail. This would make
life much easier since I currently receive mounds of stuff I only skim
when I have time.
   Lastly a short plea for less mines-better messages and more constructive
comparisons, uses, etc.
   Thanks, Scott Zimmerman

Does anyone about "term1030"? Is it compatible with UNIX like Chameleon
is? What is its availablility? Most of us getting onto the net from
home using XL/XE computers must use the Chameleon program from ANTIC.
If term1030 would do the job, I and others, would like to obtain it.

Has anyone used it?

I still do not know how the 1030 can be made to answer if it is not built
into it electronically to do so, but then sometimes software can do miracles!

So what should they have done? Intentionally charged too much for it
so they could appear to give us a good deal later on? (Sounds like
the Amiga--it may be better, but is it $1K worth of better? I don't
think so.)

A $400 computer is a toy.
A $400 computer that costs $800 is an expensive toy.
/* End of text from net.micro.atari */

Would you buy the ST at a store that bought them for $400 and sold them to
you for $2000 in a fancy plush room with Windham Hill music piped in?
(Of course not, because you know the hoi polloi can get them for $400...but
what if you didn't know?)

It is function that determines toy status, not price--unless you're of the sort that judges quality by price.

James Jones

Ok Sherman, set the Wayback for 15 years.
Now, it is 1971 and I have an ST selling for $400.
Is this a toy? What are your standards? More to the point,
what is your definition of a toy? If I price a Cray at $400,
does it suddenly become a toy?

Just curious,

Donald Keen
AT&T Consumer Products

AT&T is not curious; they couldn't care less about any replies
or my questions.

Do you have any evidence for this? I have never known anyone to put
a lower limit on what they are willing to spend, just an upper limit.

> On the other hand, those who want to
>buy a $400 computer won't buy a $2000 Amiga or a $1500 Mac or a $1000
>Apple II.
>

Probably they are looking for a $400 computer because they can't afford
more.

>DIGITIZERS and FRAME GRABBERS. Facts are facts: the Amiga, when it
>matures, will be light years ahead of all its competition, technologically,
>and folks like IBM, Apple, and Atari will take at least 2 years to catch
>up to what the Amiga is now.
>
I am willing to believe this about Atari, but I would not be so quick
to count Apple and IBM out. They both have enough money to do quite
a bit of research and development of new products. Sure, IBM has been
conservative in the small computer market as far as what they sell,
but I wouldn't be too surprised to find out they have a Mac like or
Amiga like machine already developed, just in case it looks like the
market would be big enough for them. So you might have to subtract
some from that 2 years.

>I not write. However, from the E-Mail I get, Mac people want to be
>ignorant of the technology that is burying the Mac (don't post stuff to
>net.mac...), and Atari and Amiga folks LIKE MY STUFF (3 to 1). I think

Oh hell, why don't we just get rid of all these stupid newsgroups and
post everything to net.general? Look, the reason people on net.micro.mac
don't want to see a lot of Amiga discussion (or ST discussion) in
net.micro.mac is that that is not what that newgroup is for! We come
over here to see the Amiga stuff, and we go to net.micro.atari for the
ST stuff. How would you like it if mod.computers.sun was diverted into
net.amiga (since a Sun is "better" than an Amiga)?

Don't forget some of the really good ones, like the switcher, newer debugged
finders, even BASIC, over in net.micro.mac

For some reason, the folks in net.micro.amiga seem to have few of the
hassles over posting sources to the distribution group that seem to
show up in this list.

Also, commodore has actually provided a knowlegable company person
to give INFORMED ANSWERS to important questions. Not to tout his
product, just to prevent the spread of mis-information.

Seems like we could use a little accurate information over here.

Seems that this early in the introduction of a new product, just about
ANYTHING posted to this group should be considered a blessing.

(Besides, we can always use a dis-assembler to see how it works).

I would rather see some meaningful source code, but post whatever you
feel you can!

Has anybody successfully ported any of the Amiga code over to the ST?
Someone ported some of it to their CoCo/OS-9 system (see net.micro.6809).

We're getting baited into wasting net space/money on some useless debates.

Lets get some of the REAL issues out there. Like:
1: which chips are socketed (CPU?)?
2: who knows how Atari is going to implement X3T9 (SCSI) out the DMA port?
3: Is there a good debugger?
4: Are applications 'taking over' the operating system (Like they do with
MS-DOS?)?
5: Are System Calls Re-Entrant? (If so, true multitasking may be possible)
6: How much of the OS is in ROM? Can vectors be remapped?
7: Are the ROM's modular (Can I replace one with a new boot driver, or
     Do you have to replace the works? Could one replace the trap
     handler to allow use with a 68010?

8: Anybody tried using a Track-Ball instead of the mouse?
9: Can you order spare cables (to cut up and make standard connections)
10: Other than the new ROM provisions, any other board revisions noticed?
11: Is there a way to produce "standard format" graphics data files so
     that text->graphics applications can be made possible?
12: Are atari representatives available to answer technical questions?
13: What would you most like to see in the next version of the machine?

One magazine article and some E-mail directly to me indicates that Atari
will (has) implement(ed) X3T9(SCSI) protocol in the new ROM (confirmations?).
Appearently, there is a small expansion box required (the DMA port does not
support full SCSI arbitration). SCSI has provisions for DISK, Printer,
CPU-CPU communications. SCSI even has provisions for remote file/systems
with high levels of intellegence (Like I/O to-from a UNIX box) with features
like 'search for pattern', though not all peripherals support it.

The SCSI standard is actually "ANSII Standard X3T9-2" and can be obtained
from engineering libraries, the National Bureau of Standards, ANSI, or
Mini-Micro Systems. MMS provides this on a 5 1/4" floppy in IBM-PC format.
The others provide it printed. Many are expecting (hoping) that SCSI will
replace RS-232 as the general purpose interface standard.

Full SCSI (I don't know what Atari's final plans are), allows a very
low cost network of up to 8 devices. Any combination of printers,

CPU's and Drives (SCSI), may be used. SASI drives may be used as well,
but probably not in network configuration. SCSI is intended to be
a true 'Generic Buss', eliminating normal interface problems such as
timing, protocol, and data-bus width (SCSI is ALWAYS 8 bits wide).

If Atari implements FULL SCSI, the interfacing problems associated with
drives and special peripherals are reduced significantly. Full SCSI
is even simpler than GPIB protocol. The first request is "What Are You",
(Inquiry). Then read block 0, to boot.

A quick summary is as follow
Basic Format of Commands(Transactions)

Keywords: microEmacs
Summary: microEmacs available for 520ST

I will be posting the source code for the MicroEmacs in the next few
weeks. It contains minor, but many, improvements, including bindings to
function keys (F1-F10), the HELP-UNDO group, and the numeric key pad.

  I ported it from the sources that were posted on this net. If you
can't wait, or do not have the C development system that you need to
compile it, send me a SASE and a diskette for a copy of it.

Below is what OSS says about turning their bank-select ROM cartridges
(BASIC XL, MAC/65, Action) on and off (uncovering RAM) without
confusing the OS.
     Note that remarks about location 3FAh may not be needed for
other than DOS/XL; it is not mentioned in my OS documentation and
I have not experimented.
     If you are using DOS XL with the option that puts most of DOS
in the address space occupied by the cartridge, then you better
not select out the cartridge and mutilate that RAM!

From OSS bbs (408) 446-3451:

Re: Turning Our Carts ON/OFF (S. Grimm)
9/16/85 12:00:00   size: 772

  Sorry that it took so long Steven, but we've finally compiled the right
way to turn the carts on and off:

To Turn a SuperCartridge OFF:
 1 Close Channel 0
 2 Wait for the LSB of the clock (20) to change value.
 3 Do an SEI
 4 Save $AFFF so that you can restore the cart to its previous state.
 5 STA $D508. This turns cart off.

 6 Poke $3FA,0 to tell OS that there is no cart.
 7 Poke $6A,$C0 (RAMTOP) to tell OS that more RAM is available.
 8 Do a CLI
 9 Open #0,12,0,"E:"

To Turn a Supercartridge back ON:
 1 Perform steps 1-3 from above.
 2 LDX with value saved in 4 above.
 3 STA $D500,X. This turns cart on.
 4 Poke $3FA,1 to tell OS that there is a cart.
 5 Poke $6A,$A0 to tell OS that less RAM is available.
 6 Perform steps 8-9 from above.

I'll concede your point. My wording was careless. But consider:
(1) Deep Blue C is not at all a complete implementation. So your challenge
programs may not compile with it anyway.
(2) I have readily translated C utilities to "Action", taken e.g. from
/usr/src (blush).

I think the experiences described in trying to return a slightly defective
machine to a computer specialty store is another reason why selling the
520ST through mass merchandisers makes sense. As was very stated in an
earlier posting, specialty stores work on low volume, high priced, high
margin sales. The 520ST is just barely expensive enough to support the
specialty store. The stores I have seen a 520ST in looked like they would
have trouble getting an IBM franchise so they were probably scraping by
with what they could get. Having to accept a return would probably be
a serious hardship for a specialty store.

The mass merchandisers work on high volume, low to moderate priced, very
low margin sales. They offer little to no in-store selling. If a product
like the 520ST can "sell itself" it is a very welcome item for the mass
merchandiser. The mass merchandiser can offer one thing that would flatten
a specialty store and which is of very great value -- very liberal return
policies. The one I am especially fond of is Target's "if you aren't
happy, we'll give you your money back" policy but it isn't that much
different from others. (I just returned a VCR that had problems with
playing LP tapes 2 1/2 months after I bought it. No hassle -- "sorry
about the problem". I would faint if a specialty store did that.)

In all fairness we should examine what the specialty stores have done for
Atari. While I'm sure some of them have been selling their hearts out,
I'm sure that a lot haven't. Beyond that, no matter how hard they try
they don't have the resources to handle the type of sales volume that
the 520ST needs given the way it is positioned in the market. It is
clear that Atari had to use the specialty stores to get the ball rolling.
I think keeping the 520ST out of K-Mart until after Christmas and giving
them the 1040ST is a pretty fair shake. Anyone who was surprised by the
520ST going mass market just isn't awake enough to be in business, especially
the computer business.

Disclaimer: All the above opinions are mine alone as should be obvious
             to all who are following the outcries about the Atari
             marketing strategies.

>--
I usually reply to such things privately, but this frustrating problem comes
up with the developer's kit enough to warrant posting a reply. For those
without the developer's kit, I beg your patience.

For some reason, the "gemstart.o" (or gems.o) module deallocates all but about
1K of user stack/heap space. Thus, you can have a 1 meg machine with 3/4 meg
free, and still get the out of memory message. I ran into the same problem
with Pexec() and had other problems as well, until I modified gemstart.s to
allocate more space. Then the problems went away and I could get on with my
work. I don't have the code at hand, so I can't give the exact fix. But
somewhere there is a constant (400 or 500 hex) which gets added to the end of
the program area. The stack is reset at this point and the rest of memory is
deallocated. You get to use the space between the end of your code and the
stack pointer. (400 or 500hex bytes)

A friend has decided to add a printer to his 800 (not XL).
Except for some old hacks at using the joystick ports, I believe
the only way to hook a parallel printer is via an 850 interface.
He has an Okidata M93 microline printer on his IBM PC that he is
willing to hook to the 800, but wonders if it will merely be a
cabling issue once he has an 850? Otherwise, what's an 80 column
dot matrix printer (under $200) that can be hooked to the 850?
Please reply directly to me: Lazear@Mitre.ARPA

P.S. Anybody got an 850 they would part with?

21-JAN-1986

A few questions for whoever can answer them:

-- Anyone know if there are/will be any Lisp compilers for the ST?

-- Developers: I have read recent complaints on net.micro.amiga on the Amiga's opsys. Do you have any similar complaints of non-standard IO, too-detailed use of opsys procedures to do simple things etc.

: Is GEM's VDI or whatever produces the graphical interface similar to IEEE Graphics Kernal System (GKS) and related standards? Can I easily modify programs using GKS primatives (procedures) for GEM? Or will I have to wait for someone to port that standard to the ST.

Thanks in advance.

Below is what OSS says about turning their bank-select ROM cartridges
(BASIC XL, MAC/65, Action) on and off (uncovering RAM) without
confusing the OS.
     Note that remarks about location 3FAh may not be needed for

other than DOS/XL; it is not mentioned in my OS documentation and
I have not experimented.
     If you are using DOS XL with the option that puts most of DOS
in the address space occupied by the cartridge, then you better
not select out the cartridge and mutilate that RAM!

Re: Turning Our Carts ON/OFF (S. Grimm)
9/16/85 12:00:00   size: 772

  Sorry that it took so long Steven, but we've finally compiled the right
way to turn the carts on and off:

To Turn a SuperCartridge OFF:
 1 Close Channel 0
 2 Wait for the LSB of the clock (20) to change value.
 3 Do an SEI
 4 Save $AFFF so that you can restore the cart to its previous state.
 5 STA $D508. This turns cart off.
 6 Poke $3FA,0 to tell OS that there is no cart.
 7 Poke $6A,$C0 (RAMTOP) to tell OS that more RAM is available.
 8 Do a CLI
 9 Open #0,12,0,"E:"

To Turn a Supercartridge back ON:
 1 Perform steps 1-3 from above.
 2 LDX with value saved in 4 above.
 3 STA $D500,X. This turns cart on.
 4 Poke $3FA,1 to tell OS that there is a cart.
 5 Poke $6A,$A0 to tell OS that less RAM is available.
 6 Perform steps 8-9 from above.

To: Jeff Van Epps - your return address is too long for my mail system.

Jeff,

I had the same problem with Compuserve and Hometerm. I found an advice
file on Compuserve which mentioned interference from the printer (or
printer driver). I unplugged my parallel printer from the 850 interface
BEFORE booting. It worked. If you are superstitious give it a try.

                            -Brenda

An interesting point was brought up in net.games.video recently. Apparently,
some people aren't aware that when Tramiel bought the Atari Home Computer
company, he did NOT also get the Coin-op division (which was profitable).
Anyway, there was a third division called AtariSoft, which developed games
for ALL home computers. Did Tramiel get AtariSoft, too? If he did,
does that mean that we can all expect to see the 520 ST get games like
Defender, Robotron, and Pac Man (while the Amiga doesn't, presumably)?

As an aside, Atari was once a $2 Billion company. When Tramiel bought it,
he put little money down, assumed a large amount of debt (which a few
people I know didn't get paid) - al for $75 Million... what a downfall.
On the other hand, Commodore lost $318 Million last year.

There are sometimes good reasons for making binaries freely
available but not sources. In the case of Megaroids, it is
probably in the best interests of Megamax to not distribute the
source for free. Since the purpose of Megaroids is to advertise
the Megamax C compiler, they probably want to avoid having N
buggy versions of Megaroids floating around, which they would
have if source were commonly available, because people would
modify it and then distribute the modified versions.
~~~~~~~~~~~~~~~~~~~~~~~~

Also, they might have some time critical stuff as inline assembly
language. This would tend to make it hard to compile on other C
compilers unless they both use the same format for inline
assembly. Since they want Megaroids to be available to people
who don't have Megamax C (yet!), binary is the way to go.

Are there any terminal emulators available for the ST that emulate a "smarter"
terminal than a vt52 or vt100? Even at 1200 baud, using a full-screen editor
like EMACS on a vt100 is positively painful. What I'd like to see is something
that has an insert character mode and that can insert and delete lines in
the middle of the screen, so that EMACS doesn't have to redraw the whole
screen whenever you type anything. (In other words, I'm looking for a
replacement for my H19 terminal!) Or does the vt100 emulator actually
emulate a vt102?

I'd just like to comment that when I upgraded to one meg I noticed that
the two ROMs currently installed had what looked like DIODES (zeners ??)
across power and ground. The empty sockets did not. Will these have to
be added ?

I would assume that (for those who have the source) it would not
be too hard to upgrade a vt100 emulator to a vt102 (or for that
matter, a vt52 emulator to h-19.....the only difference in each
case is the addition of real insert/char insert/line function.)

Does anyone have the source for any of these terminal emulators?

> know the software proceedure for getting the cartridge to swap?
> Perhaps writing to a particular address in the cartridge address
> space?

The "SuperCartridges" make use of the CARTSEL (?) line at $D500.

Typically, the lower 4K of cart space are switched ($A000-$AFFF).

Location $AFFF contains the current bank number (I think....).

To switch, simply load the bank number in X, and store the accumulator
at $D500 X indexed.

Bank 8 switches out the complete cart to make RAM available (all 8K).
Selecting any valid bank restores the cart.

e.g.:   select bank 0

```
     LDX #0
     STA $D500,X

     select RAM

     LDX #8
     STA $D500,X
```

Dont't forget to worry about the display location and OS database when
making the cart appear and disappear....

As a former retail person representing the old Atari and Commodore
line when they first came out, I have to respond to this.

When a computer come out for what appears to be a rediculously low price,
Specialty Computer Stores are skeptical, cautious, and greedy. The profit
margin (in dollars per unit) is much lower for a computer selling for
say $1000 than for a comparable (or even inferior) machine selling for
$2000. The pressure on the sales people comes from two directions.

The Store wants to make a better "per unit profit" to pay expenses, therefore
salesmen are encouraged to sell more expensive machines and discourage

people from buying the less expensive ones.

Competitors, also discouraging sales of "cheap" computers, will tell some whopping lies if necessary to prevent the customer from going to another store where they sell "game machines" and buying a "toy computer". In fact, when Atari was selling computers to schools at 3 for the price of 2, one school board dismissed the Atari as a game machine and removed the merchant from the bidding list.

If Atari had come out with a VAX 11/780 running full UNIX 4.3 for $300, the IBM-PC merchants would have called it a "game machine" or a "toy computer". How do the ST dhrystone tests compare with a 11/750?

Stores like K-Mart are more concerned with Volume sales. They would rather sell lot's of $300 computers than just a few $2000 boxes. The salesmen in some stores are even more qualified than those at the Specialty shops, but even if they're not, there is less pressure to get "commission" from a $3000 package.

I have actually seen two local stores go bankrupt snubbing the ST. The industry moans and gripes about the "Slump" in computer sales, yet when a computer that could potentially turn the "Slump" into another "Boom" comes around, the retailers and pundits treat it like a "toy". There have been several computers in the under $1000 market, several of them were "PC Clones" that were "Less than 100% compatible". Now Commodore and Atari have created machines that are an order of magnitude more powerful than "The Original", and they have been declared "Home Computers", "Game Machines", and "Kid's Toys", but "Not for Serious Business Use".

The Amiga is getting the "Prestige Treatement" because it has a price tag that people normally associates with "Real Computers". Of course, Commodore proved that "Good Press" and high volume are not mutually exclusive.

The Important thing for Retailers and the industry as a whole to consider is this:

    For every ST sold, there is one IBM-PC (or clone) that wasn't.

Even though the "PC-Cloners" don't consider the ST a direct competitor, as more people discover that an ST can do the same "Big 5" business applications as well or better than "IBM's Finest", the customer is going to start asking for a "Home Computer" rather than a "Business Machine".

Anybody remember when "Business Computers Run CP/M" was the means of discouraging people from buying Atari's and Commodore's.

At $800, Atari has already sold 100,000 ST's in less than 6 months and the software has only now started coming. At $300-$400, Atari may sell 100,000 units per MONTH. Even if the computer stores snub atari completely, this is a terrific candidate for software that is sold in record shops, typewriter stores, or even K-Mart. "Yes K-mart shoppers for the next 10

minutes our blue light special will be System V UNIX for the 520ST for
only $19.95! Come and see our other fine software".

On the flip side.

K-Mart has been very reluctant in the past to sell any software other
than that labled by the computer manufacturer. Getting K-Mart to sell
your software is a little more difficult than getting it into your
local "Computer Shack". If K-Mart does sell your product, you can
expect a minimum of 10,000 copies just to get started.

uuencode/uudecode are encoding schemes which allow binary files
to be converted to/from text format files. The format is similar to
"Intel Hex" or "Motorola S-Record" format but requires about 1/3
less disk space.

Source for these utilities was submitted to the net about a month
ago.

If you are connected to a unix system:

save the file to some temporary name like "asm68k.uuc"
then run the following command from the shell.

uudecode asm68k.uuc

the file will now be in binary format so that you can use kermit
or xmodem to transferr it directly to your ST disk.

This method has 3 advantages:
  1: files can be decoded on a unix host or on an ST
  2: binary files decoded on a unix host take less time to transferr
  3: longer, more complex programs can be sent over the mail/net before hitting
     the "size limit".
  4: Cost of transferring files through the "Back Bone" of the net is lower.

**** "They eat lions, don't they?" - film title ****
     On the subject of timer A in the 78901 chip, I checked out the entire bios code that is executed upon entry to xbtimer from start to finish. And it all seemed to be beautifully in accord with the specifications for the timer chip. I was just about to give up when I read in the bios manual that some tricky business with the Hsync interrupt could be done by faking RTEs. Then I realised that timer interrupts put a short stack frame onto the supervisor stack. Which means that an RTE in Super mode is required. A C program return can presumably only ever be an RTS. Hence the program can not possibly work by diverting the timer interrupt to a C function as an interrupt handler.
     First, can anybody out there confirm my brief analysis of the problem. Second, has anybody discovered the means of RTEing at the end of a C program? The bios manual defines xbtimer as a C program. But it doesn't mention anything about having to write an assembly language program to handle timer interrupts. Many of you must have long ago written programs to handle such interrupts. So please tell me if I am incorrect in all of this. Thanks.............................ak.

I agree with the basic premise that those who have been buying the ST initially
have been primarily developers. Those developers can get be "appeased" best
not by rebates for or "free upgrades" but by getting help from Atari in getting
their software (even some of this "public domain stuff") onto the shelves of
stores like K-Mart. The profits from software sales to non-developers
would pay for the new machines several times over.

I mention "public domain" because their are those who would rather "buy
it off the shelf" than get it off of compuserve, because it is hard to
find what you are looking for on a 300 baud modem. I've seen a "public
domain" ram-disk on this net, and seen the same basic package sold over
the counter for $15. It sells well as an "Impulse Item" that doesn't
require a lot of "pitching".

Perhaps Atari will put an "electronic software store" on-line via
telenet or something so that shoppers aren't paying $6.00/hour to "Read
the Ads", but they could Buy the Software for $6-$20 using their VISA.
The Software could be down-loaded, just like any other bulletin board,
but the documentation, micro-floppy... could be sent via regular mail
or picked up at a local "specialty store" in two or three days.
Of course they could still pick up $1-$2/hour for "just browsing" and

still be a "Nice Place to Shop".

I would like to tell you folks about a couple of assembler/compilers
I wrote for a real nice structured programming language for the 6502.
First, however, a little background.

I am a video game programmer with several years experience. I also was
probably the 2nd person to use the Lattice 'C' compiler almost 10 years
ago (it wasn't for the 8086/88 family yet), so I have a bit of 'C'
programming experience. I have noticed a real absurd notion among some
people that video game programmers are not "real" engineers, but I think
they are the cream of the crop.

In the last 3 years, I have written over 300K of 6502 code alone, not
even including 6809, Z80, 8086, and 68000 code I had to write. On each
of these machines (ColecoVision, IBM PC, Commodore 64, Atari 800, Atari
VCS, etc.), a good program had to squeeze every cpu cycle, byte of RAM,
and byte of ROM out of every program. Some of the machines were quite
crude; the VCS had 128 bytes of RAM and 4K of ROM; the ColecoVision had
maybe 4K of RAM and 16K of ROM, etc. Some of the machines were actually
reasonable computers (C64, Atari 800) with lots of Ram and disk drives.

I think 'C' is a very good language for the average engineer (most of us

are average by definition), but is unusable for any application where speed and code size are real critical. I admit you can hand optimize, etc., 'C' programs to make them better, but such a program could never be as fast or as small as a well written Assembler language program. 'C' has its advantages, though, which every video game programmer would like to take advantage of (speed of development, portability, etc.).

This brings me to BASM. BASM is a compiler/assembler I bought for the C64, when I was looking for development tools. BASM was advertised as a Basic Compiler, and the source strongly resembled BASIC. However, upon careful examination, I found that what BASM really is is a RATFOR for 6502 assembler language (instead of fortran). The idea intrigued me, and I ended up using it for quite a bit of development. The biggest drawback of the language was that it was native to the C64, and therefore horribly slow (100 Baud serial disk drives, echhh).

What does a RATFOR for 6502 assembler language look like? Well, let's look at an example:

```
putchar=$ffd2      ; C64 Rom kernel put char to screen routine

main
   for i = 1 to 100
      puthex i
   next i
   stop            ; return to shell

 def puthex h
   lsr a : lsr a : lsr a : lsr a : tax
   putchar hextab,x
   let h and $0f : tax
   putchar hextab,x
   return
 enddef puthex

hextab data "0123456789abcdef"

  end
```

The above example will print the numbers 1 to 100 in hex. If you can read 6502 code (after all, it is the simplest of all major micros), you will recognize some assembler language syntax (lsr a tax etc.). BASM lets you mix high level constructs (while, for, if then else, etc.) with assembler language to form a very elegent ('C' eat your heart out) compact program. BASM seems to have all of the major advantages of 'C', yet it generates code nearly as well as anyone can by hand.

This leads me to some questions that I have for all the UNIX gurus out there. Is 'C' really portable, or is UNIX pretty tough to port anyway (by pretty tough, I mean a few months' work)? Are other applications written in 'C' really portable? (I bet most are near impossible to port from UNIX to the 8086). Is it worth it for portability to have

programs that run at half the speed (or less) than the computer is capable of (or will it matter if they make computers go fast enough)? Or does it make more sense to use a language that fits the architecture of the target machine (faster smaller code)? Is time better spent porting code that is not optimized for the target (but works) or is that time better spent making a more optimized program for the target? Does anyone else besides me notice that the IBM PC AT runs rings around UNIX in any environment I have seen it (PDP-11 and VAXes) - MS DOS is written in assembler language? Does anyone care how big their programs are? Does anyone care how big the runtime libraries are (BASM has no runtime library period)?

Should it matter that a language called Action (similar to BASM) on a toy Atari 800 can compile a megabyte of source code (a little overstated) in the time any 'C' compiler I have seen can compile "Hello, World"? Is portability a reality? I can port a BASM program from the C64 to the C128 to the Atari 800 to the Apple II faster than a 'C' program can be ported from Unix to the IBM PC, and we are talking about 20 MILLION machines. Will a 'C' program ever be ported from the Amiga or ST to anywhere else (the Amiga OS has maybe 400 functions not supported by Unix)? How many are worth porting the other way?

I have not been trying to flame 'C', which is a Ratfor for PDP-11 assembler language, so please nobody take this as a personal attack against some hallowed institution. What I have been trying to do is provide some food for thought for those of you out there who want to write compilers. The world needs more Modula and Pascal and 'C' compilers like we all need another hole in the head. How about using 'C' to bootstrap a new language that fits a machine's architecture reasonably.

I shudder to think of a highly structured 'C' program spending the majority of its time pushing and poping registers, passing arguments, and returning a whole byte (or word or more) for a true/false condition. It seems to me that all this time could be spent running someone else's program - allowing more programs to run (and faster). However, one of these days, disk drives will be real fast, and Ram will be real fast, and the CPUs will run at gigahertz clock speeds - then who cares (we all will even then...).

Have a heart, this stuff is my opinion, and my observations (I am entitled to my own opinion), and send any death threats, etc. directly to me via mail.

Mike Schwartz @ 3Com Corp.

P.S. BASM was originally developed for the C64 and Atari 800 computers by Computer Alliance of Granada Hills California. I wrote a functional equivalent of BASM for the IBM PC (generating 6502 code), then wrote a superset of it (included macros, and other bells and whistles). All three compilers accept straight assembler language as input.

8086 BASM:

```
 def strcpy .s1, .s2
```

```
   mov si,s2
   mov di,s1
   while [si] -> [di] <> 0
 enddef strcpy
```

```

I have been wandering if it would be possible/safer/easier to use a separate
PC-Board(s) (Like one or two of those RAM boards from Radio Shack)
and reduce the amount of hardware wiring required.

> Step  6: Orient the 520ST PCB so that you are looking at the
> solder side of the PCB (non-component side), with the row of

I assume from the "Unix without MMU" discussions that this is really
```

more of a DRAM-Controller and Multiplexor chip (Like the 6883 on CoCo's) is there any mapping/segment capability? Anyone figured out how to create one in "gate-arrays" or something?

Is it possible to get more information about the other pins on this chip? Which ones are the address/data/control?
Are there any pins (molex header?) that could be used to tap in the extra memory?

> Solder a 68-ohm resistor in series with the trace.

Are these series resistors being installed in newer boards?

Does Atari provide an internal RAM-Expansion header like the

one in the old Sanyo MBC-550?

Has anyone on Compuserve heard any more about the "ram expansion board kit"
discussed back in November?

Is Atari Still Reading This Net?

The vt52 emulation mode on atari CAN insert / delete line. You may need
to modify your termcap entry to reflect. I use emacs all the time, and
it almost never redraws the whole screen on char/line /region deletes.

*** REPLACE THIS LINE WITH YOUR MESSAGE ***
Here is a simple circuit that I picket off compuserve a while back
to hook a ST to an Analog RGB (not digital or RGBI monitors that
are hooked to Ibms and te like) monitor. I have not tred it myself,
but I have hear from other people that it works.NOTE: those
resistors are supposed to be important, so don't skip them.

From Steve Katz:
Hi again! Well... The resistors are 1.2K and are not tied to ground, but are in
line (I think thats what you call it).

```
Atari                              RGB Monitor
Pin  Signal            Signal
 7    R-------------~~~~-------------R monitor
 6    G-------------~~~~-------------G
10    B-------------~~~~-------------B
 9    H Sync------------------------H sync
12    V Sync------------------------V sync
13    Ground------------------------Ground
```

         with ~~~~ meaning 1.2K resistor (Brown Red Red).

 It works as I am using it right now! Good luck..SSFN!

You asked for source, you get source. This is a shar format posting of a terminal emulator with Xmodem transfers and Ascii file capture. We hope to improve it as time permits. We are posting it in hopes of getting your feed back to some minor problems, and your comments suggestions.

Enjoy.

XThis the first version of xmdm:
X
X    Features:
X         - Keeps up with high speed serial lines
X             (tested upto 19.2K Baud lines)
X
X         - Does'nt send ANY Xon/Xoff's in the terminal
X           emulation mode to the host. This is important
X           to us as we are all Emacs fans.
X
X         - Supports all baud rates.
X
X         - Ascii file capture.
X
X         - Xmodem Send/Receive.
X
X         - Uses large Rs232 receive buffer.
X
X         - Uses large file buffers. Will not beat your disk
X           drive to death like STTALK.
X
X         - Uses 2 screens. All local functions (prompts etc) are done
X           on a on one screen, and all host communication
X           appears and the other screen.
X
X         - Uses very conservative timeouts/retries figures.
X           Good for dealing with dogs like CompuServe.
X           If you have a very responsive host, then it does'nt
X           matter anyways.
X
X         - PD, share it with your friends. Only thing we ask for is
X           your comments, bug reports (& fixes). Of course we
X           are not in anyway responsible for any brain damage
X           it may cause.
X
X    Known Bugs:
X         - Send spurious characters when it changes Rs232
X         parameters (Baud rate, Flow Control). Normally this
X         does not cause a problem, just hit a return when you
X         get back to your host.
X
X         - When switching screens, it always homes the cursor.
X         (We would appreciate if anyone could tell us how to
X          fix this. What we are doing in the Code (routines
X          his_screen & my_screen) is pushing the cursor,
X          changing screens, doing local functions, changing
```

```
X          back to the old screen, and doing a pop cursor. The
X          HH guide says that the vt52 emulator is only reset
X          when you change rez.) This does cause inconvenience.
X
X         - Has not been extensively debugged!
X
X         - Sketchy documentation.
X
X    So why are we posting it?
X    To get your feedback on the general scheme of things (interface
Xetc.) and suggestions to fix the above bugs.
X
X    Coming Up:
X         - Kermit transfers, and remote server support.
X
X         - Key Macros and binding of keys to functions.
X
X         - Dialing Directory.
X
X         - dir, space, remove, rename, cd, change drive
X           functions.
X
X         - Code needs cleaning up.
X
X    Not coming up:
X         - Ascii file transmit. We do not see a need for this.
X
XTo compile and link:
X    Compile each .c to get  .o's
X
X    link68 [u] xmdm.68k=[gems|gemstart], <all the .o's>,osbind.o,gemlib
X    relmod xmdm
X
XIf you use gemstart, then the stack+heap size must be appropriately
Xmodified. I use 16K.
X
X    get rid of xmdm.68k
X    rename xmdm.prg to xmdm.tos to use from the desktop.
X
XUSAGE:
X    Double click on xmdm.tos and follow the first prompt that
Xcomes up. Hit the <help> key at any time to get back at this menu.
X
XCapturing files:
X    Hit the <help> key, then choose the function 'c' for capture
Xtoggle. Give it a file name when it asks for one.
X    All host data will be captured from now onwards.
X    To end capture, hit <help> and choose the function 'c' again.
XThis will terminate the capture and close the file. Capture is also
Xterminate automatically when you choose any of the Xmodem functions,
Xon file errors, or when you exit the program.
X
XXmodem send:
```

```
X    Prepare your host to receive a file using xmodem. Hit the
X<help> key. Choose the 's' function, for xmodem send, and give it a
Xfile name. If you want to terminate at this point, hit return instead
Xof entering a file name. After the transfer has begun, you may
Xterminate the transfer at any time by hitting CTRL-C.
X
XXmodem receive:
X    Prepare your host to send a file using xmodem. Hit the
X<help> key. Choose the 'r' function, for xmodem receive, and give it a
Xfile name. If you want to terminate at this point, hit return instead
Xof entering a file name. After the transfer has begun, you may
Xterminate the transfer at any time by hitting CTRL-C.
X
XExiting xmdm:
X    The program may be exited at any time by hitting the <undo>
Xkey, except in the middle of Xmodem transfers.
X
XChanging baud rates:
X    Hit <help> then choose the 'b' function and make a selection.
X
X    Currently only the baud rate can be changed by the user. The
Xother Rs232 port parameters cannot be changed.
X

     You asked for source, you get source. This is a useful utility
for use with the developers package from Atari.

```

X
X    cc [options] ... file ...
X
XCc runs the various passes of the C compiler, followed by the assembler
Xand the linker and relmod to produce an executable image.
X
XCc accepts various types of `file' arguements. Files with a `.c'
Xextension are compiled and assembled to produce object files with the
X`.o' extension. Files with `.s' extensions are assembled to produce
Xobject files with `.o' extensions. File with `.o' extensions are
Xincluded in the list of files to be linked, in the position in which
Xthey occur in the list of files. File names with no extension, or
Xextensions other than `.c', `.s' or `.o' are treated like files with
X`.o' extensions. Then all the files are linked with the default
Xstartup file START and the default libraries LIBS. The result is run
Xthru relmod to produce the executable image. The default name of the
Xexecutable image is NAME.
```

```
X
XThe default actions of Cc may be modified by specifying one or more of
Xthe following options that are interpreted by Cc.
X
X-c      Compile the file only. Don't run linker or relmod.
X        If the file name has a `.s' extension, then run the
X        assembler only. If the file name has a `.c' extension
X        then run the C compiler and assembler. If the file
X        name has any other extension, or no extension, ignore it.
X
X-w      Supress warnings from C compiler.
X
X-e      Run the macro preprocessor only, sending the result to stdout.
X
X-p      If present, specifies that the file and line number information
X        that is normally included in the preprocessed output is to
X        be omitted.
X
X-dname=def
X-dname       Define the name to the macro preprocessor, as if by
X        `#define'. If no defintion is given, the name is defined
X        as `1'. *Warning* the preprocessor converts `name' and
X        `def' to uppercase.
X
X-i d:        Allows using a different drive for the files in a
X        `#include <file.h>' statement. *Warning* Files in an
X        include statement within double quotes are unaffected by
X        this option.
X
X-s      Compile the `.c' files and leave the output assembler
X        files in corresponding files with `.s' suffixes. File
X        names with extensions other than `.s' are ignored. The
X        assembly, linker and relmod stages are not run.
X
X-f d:        Specifies the drive the assembler is to use for temporary
X        files.
X
X-llib        Use the library `lib' in addition to the default libraries
X        LIBS. Multiple -l options may be used.
X
X-o name      Name the output file name instead of the default NAME.
X        If name has no file name extention specified,
X        `.prg' is used.
X
X-n      Show what actions will be performed if Cc were to be
X        run. No execution is performed (Like "make -n" ).
X
X
XNOTES:
X
XAll the options that take an additional arguement, allow an optional
Xblank to be specified between the option and the arguement.
X
```

```
XDEFAULTS:
X
XThe following are defaults compiled into Cc. One or more of the
Xdefaults may be changed, by editing and re-compiling cc.c.
X
XSymbol       Value        Meaning
XSILENT       Defined      Echo command to console before executing.
X        Undefined   Work Silently.
X
XDEBUG        Defined      Echo command to console, but do not
X                execute command (like -n option).
X
XWAIT         Defined     Wait for RETURN to be hit at the console
X                before exiting Cc. Typically used when Cc
X                is run from the desktop.
X        Undefined   Do not wait before exiting Cc.
X
XLINKW        Defined     Wait for disk change between compile and
X                link. Typically defined when using single
X                sided drives where the C compiler and
X                assembler are on one disk, and the linker
X                and relmod are on a separate disk.
X        Undefined   Do not wait between compile or assembly
X                and linking statges.
X
XDEF_DRIVE    "a:"         Default drive on which the Ccompiler,
X                Assembler, linker, relmod and the
X                libraries reside.
X
X
XPRE_PROC"cp68.prg"  Name of the Macro Preprocessor.
X
XPRE_FLAGS    ""       Default Preprocessor flags. String must
X                end in a blank if it is not NULL.
X
XPASS1        "c068.prg"  Name of Pass 1 of the C compiler.
X
XPASS1_FLAGS  " -f"        Default flags to Pass 1. Note the blank
X                before -f.
X
XPASS2        "c168.prg"  Name of Pass 2 of the C compiler.
X
XPASS2_FLAGS  ""       Default flags to Oass 2. Must begin with
X                blank if not NULL.
X
XASM     "as68.prg"  Name of the assembler.
X
XASM_FLAGS    "-l -u -s a: " Default flags to the assembler. Must end
X                   in an blank.
X
XLINK         "link68.prg" Name of the Linker.
X
XLINK_FLAGS   "u"       Default flags to the Linker. The list of
```

```
X                  flags is comma separated.
X
XRELMOD       "relmod.prg" Name  of the Relocater.
X
XRELMOD_FLAGS ""        Default flags to the relocator.
X
XSTART        "gemstart"   Default startup file.
X
XLIBS         "gemlib"     List of libraries linked by default
X                  (comma separated).
X
XNAME         "a.prg"       Name of output if '-o name' is not specified.
X
XKNAME        "a"       NAME without the extension.
X
XNAME_EXT     ".prg"        The extension to use if a '-o name' was
X                  specified but `name' did not have an extension.
X
XCOMPILING CC
X
XSources required: cc.c, getopt.c and syserr.c.
XInclude files:    osbind.h
X
XCc may be linked as follows (assuming compiler etc on drive a:)
X a:link68.prg [u] cc.68k=a:gemstart,cc.o,getopt.o,syserr.o,a:osbind.o,a:gemlib
X
Xor Cc could be used as follows (assuming compiler etc on drive a:)
X    cc -o cc -i a: -f d: cc.c getopt.c syserr.c a:osbind.o
X
XA word about gemstart:
X    Gemstart as supplied by Atari does not have enough stack and
Xheap space for anything other than trivial programs. Edit gemstart.s
Xand change the constant $500, to a value such as $4000, that will give
XCc about 16K of stack+heap space. Then reassemble gemstart before
Xlinking Cc. Cc will not work if linked with gems.o.

> wonderful. I get the best of everything.

This won't work because the frame and scanline frequencies are totally
different. Your TV uses 60 Hz frame frequency, while the monochrome
monitor has 70 Hz. This is only a small difference, but the difference
in the scan line frequencies is too big. In monochrome mode, the scan
line frequency is about twice as high as in color mode.

So, you get one or the other, but not both at the same time. I would
highly recommend the monochrome monitor, it is much better than everything
I have seen before in this price range. The color mode is not too hot, I
could not work more than one hour in front of the screen... And your TV
will probably be worse than our color monitor, which means that you are
forced to use low resolution if you want to decipher text on the screen.

> I have a few questions about the 520 ST I'm curious about:
>
>   Speech synthesis: is there any?

No, just a simple sound chip, the AY-3-8910. Just enough for beep, bang,
crash, zap and this video game stuff.

>   Sound digitization- ditto?

Nothing, the midi-in is only for music instruments. It's not an analog
interface but a digital serial line.

>   Is it true that, by fiddling with interrupts, one is able to
> get more colors on the screen than normally?

Yes, you can intercept the horizontal sync and change the video lookup
table on the fly. This means 16 out of 512 colors per scanline.
I have not tried it, but I've seen it in a color graphics editor (NEOchrome).
They displayed about 200 different colors on a pallette in the bottom half
of the screen. I don't know if it's possible to change all 16 lookup table
entries in the horizontal sync time, they had a blank scan line between two
color rows.

>   Multitasking- is there any?

A very limitied multitasking:
There is one application process and several accessory processes (7, I think).
A process should give up control periodically to enable other processes to
run. Since the evnt_multi call, which waits for some mouse, keyboard or
timer event gives control to the system, it is fairly easy to write programs
which use it. Examples of such accessories are a digital watch, a ramdisk
program and such stuff.

>   Are double-sided disks and single-sided disks compatible/incompatible

> with each other and with their respective drives in any way(s)?

You can use double-sided drives in exactly the same way as you use single-sided
ones. In any case, get double-sided ! 360 K is far too small for any
serious work.

> Any meaningful responses appreciated-
> I still can't decide between an ST and an Amiga...

As was noted some time before, it depends on your needs. If you want
real multitasking, expandability and fancy graphics, you will find that the
amiga is your machine, even if it costs more in a comparable ram and disk
configuration. If you want good text display and much ram and don't need
hi-resolution color, the atari may be better for you.
And you should consult your bank account, maybe it's an argument for
the atari, too :-)

In addition to my last reply:

I'm able to post the CP/M-80-Emulator to the net (if our system administrator
allows this) but there is some great problem:

The emulator has its own floppy disk format and there is NO formatter program
with the emulator. The only way to make working CP/M-80 disks is, to copy
the distributet CP/M-80 floppy disk as a whole under TOS and then delete the
files on it. So the emulator is worthless without this floppy.

Summary: Binary without source is used as an ad?

In article <265@ism780c.UUCP>, tim@ism780c.UUCP (Tim Smith) writes:
> There are sometimes good reasons for making binaries freely
> available but not sources...
>   Since the purpose of Megaroids is to advertise
> the Megamax C compiler...

If the purpose of Megaroids is to advertise a commercial C compiler,
why are we paying to distribute it over the net?

Let them incur the cost of sending out their ad.

An $800 computer selling for $400 is an inexpensive computer. And if its' an
ST, its' one hell of a toy.

A $400 Mack? Now THAT's an expensive computer!
Four hundred dollars is what I've heard it costs Apple to make the Mack.

I can't resist putting my two cents worth (if that) on the "toy computer" issue. A lot of big minicomputers have "external power supplies" - they just rack mount them with the cpu. Personally, I think it's clever to package the power supply as simply as they have. My only objection is the proliferation of little transformers if you run a lot of peripherals, and there's an easy solution to that: spend a hundred bucks or so and buy an industrial grade power supply which you can mount out of sight and run cables to all the little boxes. Shucks, you can even rack mount the power supply if you want. That would only increase the price $500 or so.

If a PDP-11/70 is a toy then the ST is a toy.

Here, here, right on.

I know personally a software developer who wrote an application for the
so called throw away machine; 400, 800, 800XL, etc. He wrote Action! and
his name is Clinton Parker. I don't know how much longer the old Atari line
is going to be around, but I can tell you first hand that good ole Clint has
done alright financially with his Action! and is continuing to do alright.
There were approximately 2,000,000 machines out there who could use Action!
If only one percent of them purchased Action!, there would be proceeds from
20,000 sales and at ten dollars commission per sale, this could be $200,000
bucks. Of course if you were really a good programmer and came up with a
really good application you could perhaps reach 10% or more, really big bucks.
Of course the catch here is you have to be good and write something the people
want. No easy task, but don't blame the type of computer you are writing for
if you don't hit it big, after all it only does what YOU tell it too. 8-)

Please accept my apologies to all of you people at Atari, etc. I should
have known better. Of course, a 5 pin DIN connector was numbered by the
Germans! I work around DIN connectors and DIN spec's day in and out, I
know how crazy the PTE/VDE operate, the DIN numbering should follow.

[]

I'm having a problem using C-Kermit on RIT's 4.2bsd system to talk to
the Chameleon Terminal Emulator's Kermit on my Atari 800XL. Packets
get sent down to the Atari, but the first time it has to write to the
disk (after about 10K of data) things get messed up. Possibly the disk
I/O is taking too long and the host starts re-sending stuff before the
Atari is ready. Possibly Chameleon just gets confused. Possibly *I'm*
confused. Somehow packets start appearing on the screen. After about 10
tries, C-Kermit realizes nobody is responding and times out, leaving me
to tell Chameleon to quit file transfer and resume terminal mode. Has
anyone else experienced this? Any suggested solutions?

thanx,

Jeff Van Epps

I don't have the source of any of these, but it has already been done in some VT100 and VT52 emulators I've seen. For some reason, they do it but don't always document it. VT102 sequences exist in MacTerminal (says it's a VT100) and I think SmartCom (IBM-PC product), and a couple of other VT100 emulators I've seen who's names escape me. Has anybody tried using any of the VT100 emulators for the ST pretending it was a VT102? Maybe some of them will work.

Also, the Desktop Terminal Emulator (VT52) has escape sequences for insert and delete line already, but I don't know if they're H19 compatable. The sequences are:

     ESC L - Insert Line   ESC M - Delete Line

[There's also some other nice stuff there, such as changing colors, inverse video, and the like].

If you can add these sequences to the terminal definition for your ST on your host, you'll get much better performance out of most screen editors.

                        Randy

From "Artificial Intelligence Abstracts", vol.2, no. 11-12, Nov-Dec, 1985:

  CARTOONIST CREATES AI-BASED, INTERACTIVE COMIC STRIPS

An Israeli cartoonist has adapted AI techniques to create the first
interactive comic strip. "Biotoons," the creations of Yakov Kirschen,
contain two characters: a Jewish mother and uncle who take up residence
in a personal computer and interact with the user in novel and humorous
ways. Both appear on the screen and answer typed questions with a

variety of answers stored in the program. "Biotoons" will initially be
marketed for the Atari 5200ST (sic.) personal computer and represent
an innovative use of AI-based advances in operator-machine interactions.

Summary:

I don't think anyone has ever indicated that anyone would buy the Amiga because it has a higher price than the ST, just that people who are going to spend $2000 for a computer will not even consider the ST, or any other less expensive computer. On the other hand, those who want to buy a $400 computer won't buy a $2000 Amiga or a $1500 Mac or a $1000 Apple II.

Consider this: you own a business and are going to spend $3000-$6000 for a personal computer. The Amiga with 80MB of hard disk and 8.5MB RAM costs about the same as an AT, but there is quite a difference in the quality of the two standards (state of the art relative...). This large Amiga is a real impressive standard, and Amiga is making a standard. Atari's ST seems to be a follower of existing standards (Mac, Gem...), not the trendsetter for the next generation of computers. Not a single posting has convinced me that the Amiga will end up sitting on a shelf in my closet somewhere any faster than the ST - as a matter of fact, it seems like the ST will find the shelf years (literally years) before the Amiga will.

Amiga (and Commodore) was not at the CES show in Las Vegas, and most of the 3rd party people there had ST stuff. It may seem like a bad indicator for the Amiga, but IBM wasn't there either. Sales figures for November show that the Amiga sold 4% of the computer market and the Mac 7% (I wish I had figures for the ST). The Palo Alto Times reported recently that the ST was outselling the Amiga locally anywhere from 2-1 to 5-1 (but the Amiga isn'y going to disappear). However, the C128 outsold everything 5-1 during the same time.

Other news of note: Nintendo sold 250,000 stand alone video game machines (similar to the Atari 5200) over Christmas in a test market several east coast cities (talk about things running in circles). Also, the Aztec 'C' compiler should become the compiler of choice, but there is one problem that I have heard about with it - ints are 16 bits. A simple typedef should solve the problem, but it is somewhat unfortunate.

I think we all can expect some real exciting things from Commodore and Amiga in the future. The Amiga lacks a product that differentiates it from all the other computers around. The Mac is a fine desktop publisher, and for that reason alone (my opinion) it might be worth the price. THe

Amiga does not do all the fancy stuff yet, but there is little doubt in my mind that someone will do a MacWrite style program (how about Microsoft Word for the Amiga). The Amiga can do everything the Mac or ST or PC can do, given a little software. The other's can only do everything the Amiga can by adding HARDWARE.
can by adding HARDWARE. While other manufacturers are adding hardware to provide color (color monitors, graphics boards), speech (votrax), and music (MIDI), Amiga owners will be adding hardware like STEREO AUDIO DIGITIZERS and FRAME GRABBERS. Facts are facts: the Amiga, when it matures, will be light years ahead of all its competition, technologically, and folks like IBM, Apple, and Atari will take at least 2 years to catch up to what the Amiga is now.

I do not mean any of what I said above to be criticism of any of the other machines. Rather, I tried to present facts and details of the Amiga (and used other computers for comparison). I don't think I need to defend my purchase of the Amiga to anyone but myself (and I don't have a single regret), and I don't think that ST owners need to defend theirs. Amiga vs. ST is a silly debate, since neither threatens the other in the marketplace, and the similarities between the two only consists of WINDOWS, the MOUSE, and the 68000. Beyond these features, the two machines are very different. I don't think that the Amiga is a better machine (I also don't think that the ST is a better machine), although it is (ST is too...) much better than the IBM PC standard and the hardware is better than the Mac (software is a different story). I do think the Amiga is the most advanced technology you can buy for under $5000, but the ST is damn good, too (at even the same price as the Amiga).

I was tempted to stop writing things to post to the newsgroup, because I am pretty much a novice, and a few people have posted public requests that I not write. However, from the E-Mail I get, Mac people want to be ignorant of the technology that is burying the Mac (don't post stuff to net.mac...), and Atari and Amiga folks LIKE MY STUFF (3 to 1). I think this indicates that net.micro.amiga means more to some people than just a place to get free software (a real selfish attitude in my opinion). My feelings are that the ST vs. Amiga type debates are of interest to a lot of people (look at all the responses), and to a few they are a bore. IF YOU DON'T WANT TO READ ALL OF net.micro.amiga, USE THE DAMN 'N' key and skip the stuff you don't want to read. Or send me nasty E-MAIL - if I get enough, I WILL STOP.

P.S. I would like to see more graphics oriented discussions posted to the newsgroup. Has anyone used the ROM Kernel Graphics and Animation routines yet? A neat program to post would be a "sprite" or Blitter Object editor with animation. Something like IconEd, except that by sequencing through a set of patterns over time, animations can be produced. I know quite a bit about graphics and animation and sounds, from doing several C64, ColecoVision, VCS, and Coin-op games, and I am willing to share my expertise. However, I won't have time to do a whole lot of programming on my Amiga for a few weeks, so I won't be able to investigate these routines myself. However, if someone needs some assistance, send me E-MAIL, or post questions to the net. If I can't answer the questions, a lot of guys at Amiga will probably jump at the

chance to help. The area of graphics and animation seems to be the one area that noone has done any major work (Mandelbrots is neat, but it did not use any of the gels, etc.). Multi-tasking via the Exec routines would be nice, too.

In article <434@l5.uucp> gnu@l5.uucp (John Gilmore) writes:
>
>If the purpose of Megaroids is to advertise a commercial C compiler,
>why are we paying to distribute it over the net?
>
The point I was making is that Megaroids is freely distributable in
binary, but that the source is not freely distributable, and that there
are legitimate reasons for Megamax to have done it this way.

Note that Megamax did not distribute Megaroids on the USENET, someone else
did. We are paying to distribute it because someone who had it decided
that it was a reasonable game, and wanted to share it. I don't think that
the fact that Megamax released it in order to help C compiler sales is
relevant.

From Friday, 17 January 1986's Times-Tribune:

New Atari Resignation

Departure of Montross linked to Tramiel's sales strategy

By Ken Siegmann, Times Tribune staff

For the third time in four months, another executive has resigned from Atari Corp.

Albert Montross tendered his resignation as vice president and general manager while Atari was unveiling its new computer at the Consumer Electronics Show in Las Vegas last month.

Montross said he is leaving for personal reasons.

But a source close to the Sunnyvale-based personal computer company said Montross was angered over Atari Chairman Jack Tramiel's decision to sell computers through mass merchandise outlets, such as K mart.

Atari executives count not be reached for comment.

Montross joined Atari in September, shortly after the resignations of two other top executives.

James Copland, former marketing and sales vice president, and Sig Schreyer, former operations manager of U.S. operations, quit then.

Montross, a former computer retailer, said in November that he was hired to sell Atari's 520 ST computer to computer specialty stores.

But Tramiel's past dealings with computer dealers made it difficult for Atari to establish credibility in that distriution channel, industry observers have said.

While serving as chaisman of Commodore International Ltd. Tramiel infuriated specialty dealers when he dropped the price of the Commodore 64 and began selling it through mass merchandisers. Dealers were stuck with a machine that cost them more than it was selling for in toy stores.

After selling the 520 ST through computer speciality stores since July, Tramiel announced at the CES show that he would move it through mass merchandisers at a reduced price. Atari also introduced a more sophisticated machine for specialty dealers.

The move met with mixed reactions from dealers.

Ralph Gilman, vice president of market researcher InfoCorp in Cupertino, said that mass merchandisers have shown little interest in Atari's computer, at any rate.

"The mass retailing people don't want to talk to Atari right now," he said.

InfoCorp estimates that Atari sold only 850 units of the 520 ST in December. By comparision, Gilman said, Apple Computer Inc., Atari's chief rival, sold 100,000 of its Apple II computers last month.

A number of people have been wondering about hooking up their ST to a non-Atari RGB monitor. I have successfully done this, with little difficulty. Since I was unable to locate one of those strange connectors used for the video, I opened my box and found the necessary signals readily accessible. Directly behind the video connector inside are 3 rows of pads, with each of the 3 rows tied together (for whatever reason). Each row has the R, G, B, VSync and Hsync signals. Unfortunately I can't seem to find the layout, but it's pretty easy to trace. Also, there is no ground on the pads, so you'll need to grab it elsewhere. The pads are on .1 centers, so you can use BERG pins and a harmonica connector with ribbon cable to bring it out. There is some blank space between the pins, so it looks (as I recall) like:

OOO O OO

or thereabouts. The monitor I used was a BARCO GD33 analog RGB. It required composite sync, so I tied the Hsync and Vsync together through 330 ohm resistors to achieve this. Also there is no audio on this monitor, so for now

I'm doing without till I kludge something together. I imagine most medium resolution analog RBG monitors should work without much trouble.

As far as also being able to use the monochrome monitor, no real problem there. A signal (grounded Monochrome Detect) from the mono monitor signals the ST to go with monochrome. The RGB can remain hooked up, but the RGB signals are turned off resulting in a blank screen. To use color, just unplug the mono monitor cable and reboot.

Note the RGB signals have a peak amplitude of about 1.7 volts, while the sync (as I recall) is TTL.

A local group is developing a RGB to color composite video converter. It was demoed at a recent user'g group meeting and seemed to work fairly well.

I have a composite to RGB converter I use with my Atari 800, and as a TV monitor, which works very well. I suspect it would work well with the ST color monitor too. If I can ever track down the Atari video connectors, I may build some boxes based on the board I am using. Or sell the board seperately. Either video conversion is expected to run about $100-125.

Since I can't post news to the net directly for the moment, please forward any questions or remarks to me at:

The 520ST went in Germany on sale on mid August. At this time the 520ST met the regulations of the "Deutsche Bundespost". The sales figures 'til the end of the year say, that there are a few 10000's of 520ST sold. Here in Germany it is at the moment the best selling professional computer (better than PC, XT, AT or MAC and Apple][).

  > I'm able to post the CP/M-80-Emulator to the net (if our system
  > administrator allows this)

To avoid understandable flaming: None of our users has to seek special
permission before posting things. But we don't mind considerate users
asking befor they put out nx100KB of sources.

  > So the emulator is worthless without this floppy.

I know some things about CP/M Disks myself.
I guess we will write a short program that runs under TOS and writes
a CP/M disk image with a CP/M Kermit on it. There are some TOS<->CP/M
file conversion programs on that emulator disk, but we couldn't get
them to run properly.

Any suggestions on how to handle this are welcome. We are not CP/M
experts.

Is this really not available in the US?

I thought it might be a good idea to inject here what the outside world thinks about the Amiga and 520 ST. Following is an excerpt from the January 1986 IEEE Spectrum:

"COMPUTERS FOR ART, MUSIC, BUSINESS

The only players with new entries in the home computer market in 1985 were Commodore Business Machines Inc. of West Chester, Pa., and Atari Corp. of Sunnyvale, Calif., and both entries came late in the year. Atari first demonstrated its ST series of computers last January but did not ship any to dealers until the end of the summer. Commodore introduced its Amiga computer in July and began shipping about two months later.

"Both computers use a Motorola 68000 as a central processing unit, come with a mouse, and feature a windowed display. Atari's 520ST, which has 512K RAM and a 400K external 3.5 inch disk drive, retails for $799 with a monochrome monitor and $999 with a color monitor. It has a palette of 512 colors and can support 16 colors in its low-resolution mode (320 by 200), four colors in its medium-resolution mode (640 by 200), and is monochrome in its high-resolution mode (640 by 400). Thanks to Digital Research Inc.'s GEM operating environment, the display looks like a color Macintosh and is thus nicknamed Jackintosh, for Atari head Jack Tramiel.

"Commodore's Amiga gets its power from three custom chips in addition to the 68000 CPU. It comes with 256K RAM, internally expandable to 512K and externally expandable to 8 megabytes, and an 880K internal 3.5 inch disk drive. It retails for $1295 without a monitor and $1795 with a color monitor. The Amiga has a palette of 4096 colors and supports 32 colors in its low-resolution modes (320 by 200 or 320 by 400) and 16 colors in its high-resolution modes (640 by 200 or 640 by 400) [Fig. 4 [The "Mandril," an image traditionally used to show off computer graphics systems and monitors (the fine hairs beings particularly difficult to render) is shown here as created by the Amiga computer.]]

"Like the ST and Macintosh, the Amiga can display numerous functions in windows on the screen. But on the Amiga, up to 50 windows can be active at once, running various programs, while the ST and Macintosh can have only one active window.

"With graphics and animation capabilities unsurpassed by any other microcomputer, and the ability to synthesize both music and voice, the Amiga is being promoted as a machine with the "creative edge." It can also double as a serious business machine because it is IBM-compatible. The compatibility is not achieved by strapping another processor onto the machine, as other computer manufacturers do, but rather by loading software that emulated the IBM PC, down to its monochrome monitor. And the Amiga has earned the interest of the CAD/CAM market, with employees at Los Alamos National Laboratory alone purchasing over $60000 worth of the machines for that application.

"By late last year, Atari had reportedly shipped some 50,000 STs. No sales figures for the Amiga were available, but Commodore said its 700 dealers have been selling the machines so fast that retailers are maintaining waiting lists, and "every machine that comes off the line has someone's name on it." If there is a market for a "home" computer after the slump, one of these machines will find it."

Well, this article definitely influenced my decision on which machine to get.

But don't forget: you also get a monitor and a disk drive for that price.
Quoting different configurations is a good way to become confused (as well
as an unethical but surprisingly effective bargaining weapon against car
dealers...)

After I sent the request for a telephone number for ATARI product service
I managed to get this one:

1 (408) 745-2367

Unlike the numbers mentioned in my 520ST warranty information, one
can actually get through (presently) on this number in one or two tries.

I would like to share my recent experiences with ATARI product service. It
should interest anyone considering buying an ATARI computer or using
ATARI product service.

I noticed that the text on my 520ST monitor "quivered" slightly after
I bought my new 520ST system. I returned it to the dealer, and they
said that they didn't notice any problem. The ^%$#%^#s even asked me
if I might have a vision problem. After that humiliation, I sent in
my system to ATARI product service to get the problem taken care of.

I sent in my CPU and monitor on December 13, and I soon received a letter
dated December 31 stating that they noticed the problem, and solved
it by swapping monitors. I was told that it would be shipped to my
via UPS.

The days went by, and soon I was obliged to call ATARI product service
to have them check with UPS to see if my computer and monitor were
lost. As it turns out, although my system was fixed and ready to
ship on December 31, because they were doing inventory in their
warehouse, it would be another two weeks until the guys in the warehouse
were caught up.

That means that my system, that could have been shipped on December
31 will be shipped in Early February (if I'm lucky!)

I feel that it is inexcusable to have a five week wait for a system
to be shipped after begin repaired. I find this unprofessionalism
shocking.

In light of my experiences, I would make two recommendations:

If you are considering purchasing an ATARI computer, decide if you are
willing to put up with this kind of senseless hassle.

If you already own an ATARI computer, I would recommend that you try
to aviod returning it to ATARI for repair.

Also, if you are wondering why your computer hasn't come back from
ATARI product service, now you know...

X; This is an example using the object-oriented programming support in
X; XLISP.  The example involves defining a class of objects representing
X; dictionaries.  Each instance of this class will be a dictionary in
X; which names and values can be stored.  There will also be a facility
X; for finding the values associated with names after they have been
X; stored.
X
X; Create the 'Dictionary' class and establish its instance variable list.
X; The variable 'entries' will point to an association list representing the
X; entries in the dictionary instance.
X
X(setq Dictionary (Class :new '(entries)))
X
X; Setup the method for the ':isnew' initialization message.
X; This message will be send whenever a new instance of the 'Dictionary'
X; class is created.  Its purpose is to allow the new instance to be
X; initialized before any other messages are sent to it.  It sets the value
X; of 'entries' to nil to indicate that the dictionary is empty.
X
X(Dictionary :answer :isnew '()
X        '((setq entries nil)
X          self))
X
X; Define the message ':add' to make a new entry in the dictionary.  This
X; message takes two arguments.  The argument 'name' specifies the name
X; of the new entry; the argument 'value' specifies the value to be
X; associated with that name.
X
X(Dictionary :answer :add '(name value)
X        '((setq entries
X                (cons (cons name value) entries))
X          value))
X
X; Create an instance of the 'Dictionary' class.  This instance is an empty
X; dictionary to which words may be added.
X
X(setq d (Dictionary :new))
X
X; Add some entries to the new dictionary.
X
X(d :add 'mozart 'composer)
X(d :add 'winston 'computer-scientist)
X
X; Define a message to find entries in a dictionary.  This message takes
```

```
X; one argument 'name' which specifies the name of the entry for which to
X; search.  It returns the value associated with the entry if one is
X; present in the dictionary.  Otherwise, it returns nil.
X
X(Dictionary :answer :find '(name &aux entry)
X        '((cond ((setq entry (assoc name entries))
X          (cdr entry))
X         (t
X          nil))))
X
X; Try to find some entries in the dictionary we created.
X
X(d :find 'mozart)
X(d :find 'winston)
X(d :find 'bozo)
X
X; The names 'mozart' and 'winston' are found in the dictionary so their
X; values 'composer' and 'computer-scientist' are returned.  The name 'bozo'
X; is not found so nil is returned in this case.

X
X 1 INTRODUCTION
X
X XLISP is an experimental programming language combining some of the
X features of LISP with an object oriented extension capability. It was
X implemented to allow experimentation with object oriented programming
X on small computers. There are currently implementations running on
X the the VAX under VAX/VMS and Berkeley VAX/UNIX, on the 8088/8086
X under CP/M-86 and MS-DOS, on the 68000 under CP/M-68K and on the
X Macintosh. It is completely written in the programming language 'C'
X and is easily extended with user written built-in functions and
X classes. It is available in source form free of charge to
X non-commercial users.
X
X Many traditional LISP functions are built into XLISP. In addition,
X XLISP defines the objects 'Object' and 'Class' as primitives.
X 'Object' is the only class that has no superclass and hence is the
X root of the class heirarchy tree. 'Class' is the class of which all
X classes are instances (it is the only object that is an instance of
X itself).
X
X This document is a brief description of XLISP. It assumes some
X knowledge of LISP and some understanding of the concepts of
X object-oriented programming.
X
X A recommended text for learning LISP programming is the book "LISP" by
X Winston and Horn and published by Addison Wesley. The first edition
X of this book is based on MacLisp and the second edition is based on
X Common Lisp. Future versions of XLISP will continue to migrate
X towards compatibility with Common Lisp.
X

X

X
X
X 2 A NOTE FROM THE AUTHOR
X
X If you have any problems with XLISP, feel free to contact me for help
X or advice. Please remember that since XLISP is available in source
X form in a high level language, many users have been making versions
X available on a variety of machines. If you call to report a problem
X with a specific version, I may not be able to help you if that version
X runs on a machine to which I don't have access. Please have the
X version number of the version that you are running readily accessible

X before calling me.
X
X If you find a bug in XLISP, first try to fix the bug yourself using
X the source code provided. If you are successful in fixing the bug,
X send the bug report along with the fix to me. If you don't have
X access to a C compiler or are unable to fix a bug, please send the bug
X report to me and I'll try to fix it.
X
X Any suggestions for improvements will be welcomed. Feel free to
X extend the language in whatever way suits your needs. However, PLEASE
X DO NOT RELEASE ENHANCED VERSIONS WITHOUT CHECKING WITH ME FIRST!! I
X would like to be the clearing house for new features added to XLISP.
X If you want to add features for your own personal use, go ahead. But,
X if you want to distribute your enhanced version, contact me first.
X Please remember that the goal of XLISP is to provide a language to
X learn and experiment with LISP and object-oriented programming on
X small computers. I don't want it to get so big that it requires
X megabytes of memory to run.
X

X

X
X
X 3 XLISP COMMAND LOOP
X
X When XLISP is started, it first tries to load "init.lsp" from the
X default directory. It then loads any files named as parameters on the
X command line (after appending ".lsp" to their names). It then issues
X the following prompt:
X
X >
X
X This indicates that XLISP is waiting for an expression to be typed.
X When an incomplete expression has been typed (one where the left and
X right parens don't match) XLISP changes its prompt to:
X
X n>
X
X where n is an integer indicating how many levels of left parens remain
X unclosed.
X
X When a complete expression has been entered, XLISP attempts to
X evaluate that expression. If the expression evaluates successfully,
X XLISP prints the result of the evaluation and then returns to the
X initial prompt waiting for another expression to be typed.
X
X Input can be aborted at any time by typing the CONTROL-G key (it may
X be necessary to follow CONTROL-G by RETURN).
X

X

4 BREAK COMMAND LOOP

When XLISP encounters an error while evaluating an expression, it attempts to handle the error in the following way:

If the symbol '*breakenable*' is true, the message corresponding to the error is printed. If the error is correctable, the correction message is printed. If the symbol '*tracenable*' is true, a trace back is printed. The number of entries printed depends on the value of the symbol '*tracelimit*'. If this symbol is set to something other than a number, the entire trace back stack is printed. XLISP then enters a read/eval/print loop to allow the user to examine the state of the interpreter in the context of the error. This loop differs from the normal top-leval read/eval/print loop in that if the user invokes the function 'continue' XLISP will continue from a correctable error. If the user invokes the function 'quit' XLISP will abort the break loop and return to the top level or the next lower numbered break loop. When in a break loop, XLISP prefixes the break level to the normal prompt.

If the symbol '*breakenable*' is nil, XLISP looks for a surrounding errset function. If one is found, XLISP examines the value of the print flag. If this flag is true, the error message is printed. In any case, XLISP causes the errset function call to return nil.

If there is no surrounding errset function, XLISP prints the error message and returns to the top level.

5 DATA TYPES

There are several different data types available to XLISP programmers.

- lists
- symbols
- strings
- integers
- floats

X
X
X

function to be applied and the cdr is used as the environment to be extended with the parameter bindings.

2. If the list is a lambda expression, the current environment is used for the function application.

3. In either of the above two cases, the remaining list elements are evaluated and the resulting expressions are bound to the formal arguments of the lambda expression. The body of the function is executed within this new binding environment.

- If it is a list and the car of the list is 'macro', the remaining list elements are bound to the formal arguments of the macro expression. The body of the function is executed within this new binding environment. The result of this evaluation is considered the macro expansion. This result is then evaluated in place of the original expression.

- If it is an object, the second list element is evaluated and used as a message selector. The message formed by combining the selector with the values of the remaining list elements is sent to the object.

7 LEXICAL CONVENTIONS

The following conventions are followed when entering XLISP programs:

Comments in XLISP code begin with a semi-colon character and continue to the end of the line.

Symbol names in XLISP can consist of any sequence of non-blank printable characters except the following:

```
( ) ' ` , " ;
```

Uppercase and lowercase characters are not distinguished within symbol names. All lowercase characters are mapped to uppercase on input.

Integer literals consist of a sequence of digits optionally beginning with a '+' or '-'. The range of values an integer can represent is limited by the size of a C 'long' on the machine on which XLISP is

X running.
X
X Floating point literals consist of a sequence of digits optionally
X beginning with a '+' or '-' and including an embedded decimal point.
X The range of values a floating point number can represent is limited
X by the size of a C 'float' ('double' on machines with 32 bit
X addresses) on the machine on which XLISP is running.
X
X Literal strings are sequences of characters surrounded by double
X quotes. Within quoted strings the '\' character is used to allow
X non-printable characters to be included. The codes recognized are:
X
X ```
X \\ means the character '\'
X \n means newline
X \t means tab
X \r means return
X \e means escape
X \nnn means the character whose octal code is nnn
X ```
X
X XLISP defines several useful read macros:
X
X ```
X '<expr> == (quote <expr>)
X #'<expr> == (function <expr>)
X `<expr> == (backquote <expr>)
X ,<expr> == (comma <expr>)
X ,@<expr> == (comma-at <expr>)
X ```

X
X
X 8 OBJECTS
X
X Definitions:
X
X - selector - a symbol used to select an appropriate method
X
X - message - a selector and a list of actual arguments
X
X - method - the code that implements a message
X
X Since XLISP was created to provide a simple basis for experimenting
X with object oriented programming, one of the primitive data types
X included is 'object'. In XLISP, an object consists of a data
X structure containing a pointer to the object's class as well as a list
X containing the values of the object's instance variables.
X
X Officially, there is no way to see inside an object (look at the
X values of its instance variables). The only way to communicate with
X an object is by sending it a message. When the XLISP evaluator
X evaluates a list the value of whose first element is an object, it

X interprets the value of the second element of the list (which must be
X a symbol) as the message selector. The evaluator determines the class
X of the receiving object and attempts to find a method corresponding to
X the message selector in the set of messages defined for that class.
X If the message is not found in the object's class and the class has a
X super-class, the search continues by looking at the messages defined
X for the super-class. This process continues from one super-class to
X the next until a method for the message is found. If no method is
X found, an error occurs.
X
X When a method is found, the evaluator binds the receiving object to
X the symbol 'self', binds the class in which the method was found to
X the symbol 'msgclass', and evaluates the method using the remaining
X elements of the original list as arguments to the method. These
X arguments are always evaluated prior to being bound to their
X corresponding formal arguments. The result of evaluating the method
X becomes the result of the expression.

X                   <fargs>     the formal argument list
X                                 this list is of the form:
X                                   ([<farg>]...
X                                    [&optional [<oarg>]...]
X                                    [&rest <rarg>]
X                                    [&aux [<aux>]...])
X                                 where
X                                   <farg>   a formal argument
X                                   <oarg>   an optional argument (default is nil)
X                                   <rarg>   bound to the rest of the arguments
X                                   <aux>    a auxiliary variable (set to nil)
X                   <code>      a list of executable expressions
X                   returns     the object
X
X
X       When  a  new  instance  of  a  class is created by sending the message
X       ':new' to an existing class, the message ':isnew' followed by whatever
X       parameters were passed to the ':new' message  is  sent  to  the  newly
X       created object.
X
X       When  a  new  class  is  created  by sending the ':new' message to the
X       object 'Class', an optional parameter may be specified indicating  the
X       superclass of the new class.  If this parameter is  omitted,  the  new
X       class  will  be a subclass of 'Object'.  A class inherits all instance
X       variables, class variables, and methods from its super-class.

X
X
X       9  SYMBOLS
X
X
X             o  self - the current object (within a message context)
X
```

X   o msgclass - the class in which the current method was found
X
X   o *oblist* - the object list
X
X   o *keylist* - the keyword list
X
X   o *standard-input* - the standard input file
X
X   o *standard-output* - the standard output file
X
X   o *breakenable* - flag controlling entering the break loop on
X   errors
X
X   o *tracenable* - flag controlling trace back printout on errors
X   and breaks
X
X   o *tracelimit* - maximum number of levels of trace back
X   information printed on errors and breaks
X
X   o *evalhook* - user substitute for the evaluator function
X
X   o *applyhook* - (not yet implemented)
X
X   o *unbound* - indicator for unbound symbols

X
X
X   10 FUNCTION DEFINITIONS
X
X   10.1 EVALUATION FUNCTIONS
X
X   (eval <expr>) EVALUATE AN XLISP EXPRESSION
X   <expr>   the expression to be evaluated
X   returns   the result of evaluating the expression
X
X   (apply <fun> <args>) APPLY A FUNCTION TO A LIST OF ARGUMENTS
X   <fun>   the function to apply (or function symbol)
X   <args>   the argument list
X   returns   the result of applying the function to the argument list
X
X   (funcall <fun> [<arg>]...) CALL A FUNCTION WITH ARGUMENTS
X   <fun>   the function to call (or function symbol)
X   <arg>   arguments to pass to the function
X   returns   the result of calling the function with the arguments
X
X   (quote <expr>) RETURN AN EXPRESSION UNEVALUATED
X   <expr>   the expression to be quoted (quoted)
X   returns   <expr> unevaluated

```
X
X      (function <expr>)  QUOTE A FUNCTION
X          <expr>      the function to be quoted (quoted)
X          returns     a function closure
X
X      (backquote <expr>)  FILL IN A TEMPLATE
X          <expr>      the template
X          returns     a copy of the template with comma and comma-at expressions
X                      expanded (see the Common Lisp reference manual)

X      SYMBOL FUNCTIONS
X
X
X      10.2  SYMBOL FUNCTIONS
X
X      (set <sym> <expr>)  SET THE VALUE OF A SYMBOL
X          <sym>       the symbol being set
X          <expr>      the new value
X          returns     the new value
X
X      (setq [<sym> <expr>]...)  SET THE VALUE OF A SYMBOL
X          <sym>       the symbol being set (quoted)
X          <expr>      the new value
X          returns     the new value
X
X      (setf [<place> <expr>]...)  SET THE VALUE OF A FIELD
X          <place>     the field specifier (quoted):
X                          <sym>                set the value of a symbol
X                          (car <expr>)         set the car of a list node
X                          (cdr <expr>)         set the cdr of a list node
X                          (get <sym> <prop>)   set the value of a property
X                          (symbol-value <sym>) set the value of a symbol
X                          (symbol-plist <sym>) set the property list of a symbol
X          <value>     the new value
X          returns     the new value
X
X      (defun <sym> <fargs> [<expr>]...)  DEFINE A FUNCTION
X      (defmacro <sym> <fargs> [<expr>]...)  DEFINE A MACRO
X          <sym>       symbol being defined (quoted)
X          <fargs>     list of formal arguments (quoted)
X                        this list is of the form:
X                          ([<farg>]...
X                           [&optional [<oarg>]...]
X                           [&rest <rarg>]
X                           [&aux [<aux>]...])
X                        where
X                          <farg>      is a formal argument
X                          <oarg>      is an optional argument (default is nil)
X                          <rarg>      bound to the rest of the arguments
X                          <aux>       is an auxiliary variable (set to nil)
```

```
X           <expr>      expressions constituting the body of the
X                       function (quoted)
X           returns     the function symbol
X
X       (gensym [<tag>])  GENERATE A SYMBOL
X           <tag>       string or number
X           returns     the new symbol
X
X       (intern <pname>)  MAKE AN INTERNED SYMBOL
X           <pname>     the symbol's print name string
X           returns     the new symbol
X
X       (make-symbol <pname>)  MAKE AN UNINTERNED SYMBOL
X           <pname>     the symbol's print name string
X           returns     the new symbol
X
```

```
X
X
X       (symbol-name <sym>)  GET THE PRINT NAME OF A SYMBOL
X           <sym>       the symbol
X           returns     the symbol's print name
X
X       (symbol-value <sym>)  GET THE VALUE OF A SYMBOL
X           <sym>       the symbol
X           returns     the symbol's value
X
X       (symbol-plist <sym>)  GET THE PROPERTY LIST OF A SYMBOL
X           <sym>       the symbol
X           returns     the symbol's property list
X
```

```
X
X
X       10.3  PROPERTY LIST FUNCTIONS
X
X       (get <sym> <prop>)  GET THE VALUE OF A PROPERTY
X           <sym>       the symbol
X           <prop>      the property symbol
X           returns     the property value or nil
X
X       (putprop <sym> <val> <prop>)  PUT A PROPERTY ONTO THE PROPERTY LIST
X           <sym>       the symbol
X           <val>       the property value
X           <prop>      the property symbol
X           returns     nil
X
```

```
X       (remprop <sym> <prop>)  REMOVE A PROPERTY
X           <sym>       the symbol
X           <prop>      the property symbol
X
```

```
X
X
X       10.4  LIST FUNCTIONS
X
X       (car <expr>)  RETURN THE CAR OF A LIST NODE
X           <expr>      the list node
X           returns     the car of the list node
X
X       (cdr <expr>)  RETURN THE CDR OF A LIST NODE
X           <expr>      the list node
X           returns     the cdr of the list node
X
X       (caar <expr>) == (car (car <expr>))
X       (cadr <expr>) == (car (cdr <expr>))
X       (cdar <expr>) == (cdr (car <expr>))
X       (cddr <expr>) == (cdr (cdr <expr>))
X
X       (cons <expr1> <expr2>)  CONSTRUCT A NEW LIST NODE
X           <expr1>     the car of the new list node
X           <expr2>     the cdr of the new list node
X           returns     the new list node
X
X       (list [<expr>]...)  CREATE A LIST OF VALUES
X           <expr>      expressions to be combined into a list
X           returns     the new list
X
X       (append [<expr>]...)  APPEND LISTS
X           <expr>      lists whose elements are to be appended
X           returns     the new list
X
X       (reverse <expr>)  REVERSE A LIST
X           <expr>      the list to reverse
X           returns     a new list in the reverse order
X
X       (last <list>)  RETURN THE LAST LIST NODE OF A LIST
X           <list>      the list
X           returns     the last list node in the list
X
X       (member <expr> <list> [<key> <test>])  FIND AN EXPRESSION IN A LIST
X           <expr>      the expression to find
X           <list>      the list to search
X           <key>       the keyword :test or :test-not
X           <test>      the test function (defaults to eql)
X           returns     the remainder of the list starting with the expression
X
```

```
X       (assoc <expr> <alist> [<key> <test>])  FIND AN EXPRESSION IN AN A-LIST
X           <expr>      the expression to find
X           <alist>     the association list
X           <key>       the keyword :test or :test-not
X           <test>      the test function (defaults to eql)
X           returns     the alist entry or nil
X

X       LIST FUNCTIONS
X
X
X       (remove <expr> <list> [<key> <test>])  REMOVE AN EXPRESSION FROM A LIST
X           <expr>      the expression to delete
X           <list>      the list
X           <key>       the keyword :test or :test-not
X           <test>      the test function (defaults to eql)
X           returns     the list with the matching expressions deleted
X
X       (length <expr>)  FIND THE LENGTH OF A LIST OR STRING
X           <expr>      the list or string
X           returns     the length of the list or string
X
X       (nth <n> <list>)  RETURN THE NTH ELEMENT OF A LIST
X           <n>         the number of the element to return (zero origin)
X           <list>      the list
X           returns     the nth element or nil if the list isn't that long
X
X       (nthcdr <n> <list>)  RETURN THE NTH CDR OF A LIST
X           <n>         the number of the element to return (zero origin)
X           <list>      the list
X           returns     the nth cdr or nil if the list isn't that long
X
X       (mapc <fcn> <list1> [<list>]...)  APPLY FUNCTION TO SUCCESSIVE CARS
X           <fcn>       the function or function name
X           <listn>     a list for each argument of the function
X           returns     the first list of arguments
X
X       (mapcar <fcn> <list1> [<list>]...)  APPLY FUNCTION TO SUCCESSIVE CARS
X           <fcn>       the function or function name
X           <listn>     a list for each argument of the function
X           returns     the list of values returned by each function invocation
X
X       (mapl <fcn> <list1> [<list>]...)  APPLY FUNCTION TO SUCCESSIVE CDRS
X           <fcn>       the function or function name
X           <listn>     a list for each argument of the function
X           returns     the first list of arguments
X
X       (maplist <fcn> <list1> [<list>]...)  APPLY FUNCTION TO SUCCESSIVE CDRS
X           <fcn>       the function or function name
X           <listn>     a list for each argument of the function
X           returns     the list of values returned by each function invocation
```

10.6 PREDICATE FUNCTIONS

(atom <expr>) IS THIS AN ATOM?
    <expr> the expression to check
    returns t if the value is an atom, nil otherwise

(symbolp <expr>) IS THIS A SYMBOL?
    <expr> the expression to check
    returns t if the expression is a symbol, nil otherwise

(numberp <expr>) IS THIS A NUMBER?
    <expr> the expression to check
    returns t if the expression is a number, nil otherwise

(null <expr>) IS THIS AN EMPTY LIST?
    <expr> the list to check
    returns t if the list is empty, nil otherwise

(not <expr>) IS THIS FALSE?
    <expr> the expression to check
    return t if the expression is nil, nil otherwise

(listp <expr>) IS THIS A LIST?
    <expr> the expression to check
    returns t if the value is a list node or nil, nil otherwise

(consp <expr>) IS THIS A NON-EMPTY LIST?
    <expr> the expression to check
    returns t if the value is a list node, nil otherwise

(boundp <sym>) IS THIS A BOUND SYMBOL?
    <sym> the symbol
    returns t if a value is bound to the symbol, nil otherwise

(minusp <expr>) IS THIS NUMBER NEGATIVE?
    <expr> the number to test
    returns t if the number is negative, nil otherwise

(zerop <expr>) IS THIS NUMBER ZERO?
    <expr> the number to test
    returns t if the number is zero, nil otherwise

(plusp <expr>) IS THIS NUMBER POSITIVE?

```
X          <expr>      the number to test
X          returns     t if the number is positive, nil otherwise
X
X      (evenp <expr>)  IS THIS NUMBER EVEN?
X          <expr>      the number to test
X          returns     t if the number is even, nil otherwise
X
X      (oddp <expr>)  IS THIS NUMBER ODD?
X          <expr>      the number to test
X          returns     t if the number is odd, nil otherwise
X
X      (eq <expr1> <expr2>)  ARE THE EXPRESSIONS IDENTICAL?
X          <expr1>     the first expression
X          <expr2>     the second expression
X          returns     t if they are equal, nil otherwise
X
X      (eql <expr1> <expr2>)  ARE THE EXPRESSIONS IDENTICAL?
X                              (WORKS WITH NUMBERS AND STRINGS)
X          <expr1>     the first expression
X          <expr2>     the second expression
X          returns     t if they are equal, nil otherwise
X
X      (equal <expr1> <expr2>)  ARE THE EXPRESSIONS EQUAL?
X          <expr1>     the first expression
X          <expr2>     the second expression
X          returns     t if they are equal, nil otherwise
X

X      CONTROL FUNCTIONS
X
X
X      10.7  CONTROL FUNCTIONS
X
X      (cond [<pair>]...)  EVALUATE CONDITIONALLY
X          <pair>      pair consisting of:
X                          (<pred> [<expr>]...)
X                        where
X                          <pred>      is a predicate expression
X                          <expr>      evaluated if the predicate
X                                      is not nil
X          returns     the value of the first expression whose predicate
X                      is not nil
X
X      (and [<expr>]...)  THE LOGICAL AND OF A LIST OF EXPRESSIONS
X          <expr>      the expressions to be ANDed
X          returns     nil if any expression evaluates to nil,
X                      otherwise the value of the last expression
X                      (evaluation of expressions stops after the first
X                       expression that evaluates to nil)
X
X      (or [<expr>]...)  THE LOGICAL OR OF A LIST OF EXPRESSIONS
```

```
X          <expr>      the expressions to be ORed
X          returns     nil if all expressions evaluate to nil,
X                      otherwise the value of the first non-nil expression
X                      (evaluation of expressions stops after the first
X                       expression that does not evaluate to nil)
X
X      (if <texpr> <expr1> [<expr2>])  EXECUTE EXPRESSIONS CONDITIONALLY
X          <texpr>     the test expression
X          <expr1>     the expression to be evaluated if texpr is non-nil
X          <expr2>     the expression to be evaluated if texpr is nil
X          returns     the value of the selected expression
X
X      (let ([<binding>]...) [<expr>]...)  BIND SYMBOLS AND EVALUATE EXPRESSIONS
X      (let* ([<binding>]...) [<expr>]...)  LET WITH SEQUENTIAL BINDING
X          <binding>   the variable bindings each of which is either:
X                      1)  a symbol (which is initialized to nil)
X                      2)  a list whose car is a symbol and whose cadr
X                              is an initialization expression
X          <expr>      the expressions to be evaluated
X          returns     the value of the last expression
X
X      (catch <sym> [<expr>]...)  EVALUATE EXPRESSIONS AND CATCH THROWS
X          <sym>       the catch tag
X          <expr>      expressions to evaluate
X          returns     the value of the last expression the throw expression
X
X      (throw <sym> [<expr>])  THROW TO A CATCH
X          <sym>       the catch tag
X          <expr>      the value for the catch to return (defaults to nil)
X          returns     never returns
X

X           <expr>      the remaining expressions to evaluate
X           returns     the value of the second expression
X
X       (progn [<expr>]...)  EXECUTE EXPRESSIONS SEQUENTIALLY
X           <expr>      the expressions to evaluate
X           returns     the value of the last expression (or nil)
X
```

10.10 DEBUGGING AND ERROR HANDLING

(error <emsg> [<arg>]) SIGNAL A NON-CORRECTABLE ERROR
<emsg> the error message string
<arg> the argument expression (printed after the message)
returns never returns

(cerror <cmsg> <emsg> [<arg>]) SIGNAL A CORRECTABLE ERROR
<cmsg> the continue message string
<emsg> the error message string
<arg> the argument expression (printed after the message)
returns nil when continued from the break loop

(break [<bmsg> [<arg>]]) ENTER A BREAK LOOP
<bmsg> the break message string (defaults to "**BREAK**")
<arg> the argument expression (printed after the message)
returns nil when continued from the break loop

(clean-up) CLEAN-UP AFTER AN ERROR
returns never returns

(continue) CONTINUE FROM A CORRECTABLE ERROR
returns never returns

(errset <expr> [<pflag>]) TRAP ERRORS
<expr> the expression to execute
<pflag> flag to control printing of the error message
returns the value of the last expression consed with nil
or nil on error

(baktrace [<n>]) PRINT N LEVELS OF TRACE BACK INFORMATION
<n> the number of levels (defaults to all levels)
returns nil

(evalhook <expr> <ehook> <ahook>) EVALUATE AN EXPRESSION WITH HOOKS
<expr> the expression to evaluate
<ehook> the value for *evalhook*
<ahook> the value for *applyhook*
returns the result of evaluating the expression

10.11 ARITHMETIC FUNCTIONS

```
X       (truncate <expr>)  TRUNCATES A FLOATING POINT NUMBER TO AN INTEGER
X           <expr>      the number
X           returns     the result of truncating the number
X
X       (float <expr>)  CONVERTS AN INTEGER TO A FLOATING POINT NUMBER
X           <expr>      the number
X           returns     the result of floating the integer
X
X       (+ <expr>...)  ADD A LIST OF NUMBERS
X           <expr>      the numbers
X           returns     the result of the addition
X
X       (- <expr>...)  SUBTRACT A LIST OF NUMBERS OR NEGATE A SINGLE NUMBER
X           <expr>      the numbers
X           returns     the result of the subtraction
X
X       (* <expr>...)  MULTIPLY A LIST OF NUMBERS
X           <expr>      the numbers
X           returns     the result of the multiplication
X
X       (/ <expr>...)  DIVIDE A LIST OF NUMBERS
X           <expr>      the numbers
X           returns     the result of the division
X
X       (1+ <expr>)  ADD ONE TO A NUMBER
X           <expr>      the number
X           returns     the number plus one
X
X       (1- <expr>)  SUBTRACT ONE FROM A NUMBER
X           <expr>      the number
X           returns     the number minus one
X
X       (rem <expr>...)  REMAINDER OF A LIST OF NUMBERS
X           <expr>      the numbers
X           returns     the result of the remainder operation
X
X       (min <expr>...)  THE SMALLEST OF A LIST OF NUMBERS
X           <expr>      the expressions to be checked
X           returns     the smallest number in the list
X
X       (max <expr>...)  THE LARGEST OF A LIST OF NUMBERS
X           <expr>      the expressions to be checked
X           returns     the largest number in the list
X
X       (abs <expr>)  THE ABSOLUTE VALUE OF A NUMBER
X           <expr>      the number
X           returns     the absolute value of the number
X

X
X       XLISP: An Experimental Object Oriented Language                Page 29
X       ARITHMETIC FUNCTIONS
X
```

X
X   (sin <expr>) COMPUTE THE SINE OF A NUMBER
X   <expr>   the floating point number
X   returns   the sine of the number
X
X   (cos <expr>) COMPUTE THE COSINE OF A NUMBER
X   <expr>   the floating point number
X   returns   the cosine of the number
X
X   (tan <expr>) COMPUTE THE TANGENT OF A NUMBER
X   <expr>   the floating point number
X   returns   the tangent of the number
X
X   (expt <x-expr> <y-expr>) COMPUTE X TO THE Y POWER
X   <x-expr>   the floating point number
X   <y-expr>   the floating point exponent
X   returns   x to the y power
X
X   (exp <x-expr>) COMPUTE E TO THE X POWER
X   <x-expr>   the floating point number
X   returns   e to the x power
X
X   (sqrt <expr>) COMPUTE THE SQUARE ROOT OF A NUMBER
X   <expr>   the floating point number
X   returns   the square root of the number
X

X
X   XLISP: An Experimental Object Oriented Language   Page 30
X   BITWISE LOGICAL FUNCTIONS
X
X
X   10.12 BITWISE LOGICAL FUNCTIONS
X
X   (bit-and <expr>...) THE BITWISE AND OF A LIST OF NUMBERS
X   <expr>   the numbers
X   returns   the result of the and operation
X
X   (bit-ior <expr>...) THE BITWISE INCLUSIVE OR OF A LIST OF NUMBERS
X   <expr>   the numbers
X   returns   the result of the inclusive or operation
X
X   (bit-xor <expr>...) THE BITWISE EXCLUSIVE OR OF A LIST OF NUMBERS
X   <expr>   the numbers
X   returns   the result of the exclusive or operation
X
X   (bit-not <expr>) THE BITWISE NOT OF A NUMBER
X   <expr>   the number
X   returns   the bitwise inversion of number
X

X RELATIONAL FUNCTIONS
X
X
X 10.13 RELATIONAL FUNCTIONS
X
X The relational functions can be used to compare integers, floating
X point numbers or strings.
X
X (< <e1> <e2>) TEST FOR LESS THAN
X <e1> the left operand of the comparison
X <e2> the right operand of the comparison
X returns the result of comparing <e1> with <e2>
X
X (<= <e1> <e2>) TEST FOR LESS THAN OR EQUAL TO
X <e1> the left operand of the comparison
X <e2> the right operand of the comparison
X returns the result of comparing <e1> with <e2>
X
X (= <e1> <e2>) TEST FOR EQUAL TO
X <e1> the left operand of the comparison
X <e2> the right operand of the comparison
X returns the result of comparing <e1> with <e2>
X
X (/= <e1> <e2>) TEST FOR NOT EQUAL TO
X <e1> the left operand of the comparison
X <e2> the right operand of the comparison
X returns the result of comparing <e1> with <e2>
X
X (>= <e1> <e2>) TEST FOR GREATER THAN OR EQUAL TO
X <e1> the left operand of the comparison
X <e2> the right operand of the comparison
X returns the result of comparing <e1> with <e2>
X
X (> <e1> <e2>) TEST FOR GREATER THAN
X <e1> the left operand of the comparison
X <e2> the right operand of the comparison
X returns the result of comparing <e1> with <e2>

X STRING FUNCTIONS
X
X
X 10.14 STRING FUNCTIONS
X
X (char <string> <index>) EXTRACT A CHARACTER FROM A STRING
X <string> the string
X <index> the string index (zero relative)
X returns the ascii code of the first character
X
X (string <expr>) MAKE A STRING FROM AN INTEGER ASCII VALUE
X <expr> the numeric expression

```
X           returns     a one character string whose first character is <expr>
X
X       (strcat [<expr>]...)  CONCATENATE STRINGS
X           <expr>      the strings to concatenate
X           returns     the result of concatenating the strings
X
X       (substr <expr> <sexpr> [<lexpr>]) EXTRACT A SUBSTRING
X           <expr>      the string
X           <sexpr>     the starting position
X           <lexpr>     the length (default is rest of string)
X           returns     substring starting at <sexpr> for <lexpr>
X

X
X       XLISP: An Experimental Object Oriented Language                Page 33
X       INPUT/OUTPUT FUNCTIONS
X
X
X       10.15  INPUT/OUTPUT FUNCTIONS
X
X       (read [<source> [<eof>]])  READ AN XLISP EXPRESSION
X           <source>    the input source (default is standard input)
X           <eof>       the value to return on end of file (default is nil)
X           returns     the expression read
X
X       (print <expr> [<sink>])  PRINT A LIST OF VALUES ON A NEW LINE
X           <expr>      the expressions to be printed
X           <sink>      the output sink (default is standard output)
X           returns     the expression
X
X       (prin1 <expr> [<sink>])  PRINT A LIST OF VALUES
X           <expr>      the expressions to be printed
X           <sink>      the output sink (default is standard output)
X           returns     the expression
X
X       (princ <expr> [<sink>])  PRINT A LIST OF VALUES WITHOUT QUOTING
X           <expr>      the expressions to be printed
X           <sink>      the output sink (default is standard output)
X           returns     the expression
X
X       (terpri [<sink>])  TERMINATE THE CURRENT PRINT LINE
X           <sink>      the output sink (default is standard output)
X           returns     nil
X
X       (flatsize <expr>)  LENGTH OF PRINTED REPRESENTATION USING PRIN1
X           <expr>      the expression
X           returns     the length
X
X       (flatc <expr>)  LENGTH OF PRINTED REPRESENTATION USING PRINC
X           <expr>      the expression
X           returns     the length
X
X
```

10.16 FILE I/O FUNCTIONS

```
(openi <fname>)  OPEN AN INPUT FILE
    <fname>     the file name string
    returns     a file pointer

(openo <fname>)  OPEN AN OUTPUT FILE
    <fname>     the file name string
    returns     a file pointer

(close <fp>)  CLOSE A FILE
    <fp>        the file pointer
    returns     nil

(read-char [<source>])  READ A CHARACTER FROM A FILE OR STREAM
    <source>    the input source (default is standard input)
    returns     the character (integer)

(peek-char [<flag> [<source>]])  PEEK AT THE NEXT CHARACTER
    <flag>      flag for skipping white space (default is nil)
    <source>    the input source (default is standard input)
    returns     the character (integer)

(write-char <ch> [<sink>])  WRITE A CHARACTER TO A FILE OR STREAM
    <ch>        the character to put (integer)
    <sink>      the output sink (default is standard output)
    returns     the character (integer)

(read-line [<source>])  READ A LINE FROM A FILE OR STREAM
    <source>    the input source (default is standard input)
    returns     the input string
```

10.17 SYSTEM FUNCTIONS

```
(load <fname> [<vflag> [<pflag>]])  LOAD AN XLISP SOURCE FILE
    <fname>     the filename string (in double quotes)
    <vflag>     the verbose flag (default is t)
    <pflag>     the print flag (default is nil)
    returns     the filename

(gc)  FORCE GARBAGE COLLECTION
```

```
X          returns     nil
X
X      (expand <num>)  EXPAND MEMORY BY ADDING SEGMENTS
X          <num>       the number of segments to add
X          returns     the number of segments added
X
X      (alloc <num>)  CHANGE NUMBER OF NODES TO ALLOCATE IN EACH SEGMENT
X          <num>       the number of nodes to allocate
X          returns     the old number of nodes to allocate
X
X      (mem)  SHOW MEMORY ALLOCATION STATISTICS
X          returns     nil
X
X      (type-of <expr>)  RETURNS THE TYPE OF THE EXPRESSION
X          <expr>      the expression to return the type of
X          returns     nil if the value is nil otherwise one of the symbols:
X                          :SYMBOL   for symbols
X                          :OBJECT   for objects
X                          :CONS     for list nodes
X                          :SUBR     for subroutines with evaluated arguments
X                          :FSUBR    for subroutines with unevaluated arguments
X                          :STRING   for string nodes
X                          :FIXNUM   for integer nodes
X                          :FLONUM   for floating point nodes
X                          :FILE     for file pointer nodes
X
X      (exit)  EXIT XLISP
X          returns     never returns
SHAR_EOF
if test 53933 -ne "`wc -c 'xlisp.doc'`"
then
     echo shar: error transmitting "'xlisp.doc'" '(should have been 53933
characters)'
fi
echo shar: extracting "'read.me'" '(2236 characters)'
if test -f 'read.me'
then
     echo shar: over-writing existing file "'read.me'"
fi
sed 's/^X//' << \SHAR_EOF > 'read.me'
XThis distribution of xlisp contains the following files:
X
Xread.me      This file
Xxlisp.doc    The documentation
X
Xinit.lsp Required initialization file. Automatically loaded by
X        xlisp on startup. Must be in the same folder
X        (directory) as xlisp.ttp, unless INITPATH is defined
X        in xlisp.h. (INITPATH if the filename for init.lsp
X        not the directory name ie. "mypath\\init.lsp" and NOT
X        just "mypath\\".
X
X        Sample xlisp programs:
```

```
Xart.lsp example.lsp fact.lsp fib.lsp hanoi.lsp hdwr.lsp ifthen.lsp
Xprolog.lsp queens.lsp queens2.lsp
X
XmakefileTo make xlisp on the Vax (unix) (also see xlisp.h)
X
Xctype.h math.h setjmp.h:
X        These .h files are for the St only. When making xlisp
X        on the Vax (unix) hide these files by moving them to
X        another directory.
X
X
Xxlisp.h      Edit first line in the file for system type (ST or Unix)
X
X    Source
Xststuff.c xlbfun.c xlcont.c xldbug.c xldmem.c xleval.c xlfio.c xlftab1.c
Xxlftab2.c xlglob.c xlinit.c xlio.c xlisp.c xljump.c xllist.c xlmath.c
Xxlobj.c xlprin.c xlread.c xlstr.c xlsubr.c xlsym.c xlsys.c
X        The file ststuff.c is St specific and is not used
X        by the Vax (unix) version.
X
X
Xxlisp.bat xlisp.inp:
X    Batch file to link and relmod xlisp on the St
X
XHow to Make xlisp on the ST
X    Compile all the .c files after editing xlisp.h appropriately.
XThen link using xlisp.bat. (You will probably have to edit xlisp.bat
Xto set up the drive designator appropriately for your system). Rename
Xxlisp.prg to xlisp.ttp.
X
XTo invoke xlisp from the desktop on the ST double click xlisp.ttp. In the
Xdialog box enter the name(s) of the file(s) you want loaded (don't enter
Xthe .lsp extention). You may ofcourse choose to supply no filenames in
Xthe dialog box, in which case simply hit <return>. xlisp.ttp will
Xautomatically load init.lsp, and then the file(s).
X
XTo load a file from the interpreter issue:
X(load "filename.lsp")
XNotice the ".lsp" extention is required to be entered here.
X
XHow to Make xlisp on a Vax
X    Edit xlisp.h and makefile appropriately and then issue the
Xcommand:
X    make install
X

Re: Article 1032, How can you go wrong with Deep Blue C?

Depends on how much your time is worth. For about $50 you can get the
Action! compiler/editor, which gives you a much faster edit/compile/try
it/edit.... cycle. The language is close enough to C that it is easy
to translate to/from.

Summary: Please post sources in net.sources!

Please do not post sources or binaries to net.micro.atari.
There are several reasons for this.

Sources belong in net.sources because many sites automatically
archive them. If you don't put them there, they will expire out of
net.micro.atari in a few weeks and be gone.

Also, sites that can't afford large phone bills can subscribe to
net.micro.atari but not to net.sources. You are costing them money
they can't afford by ignoring the posting guidelines.

Lastly, [and this part is personal opinion] I object to the posting of
binaries anywhere, including net.sources. If the program is public
domain, where are its sources? You mean the *binary* is public domain
but the source is proprietary??? Why can't I fix a bug in it if I find
one? Why can't I convert this public domain program to run on my Sun?
I'm collecting a lot of PD software for the GNU project, which aims to
reimplement Unix in the public domain. However, binaries for 520ST's
don't do the project (or the world) much good.

[]
I ask this question for a friend. Excuse the lack of technical detail.

He is running C as supplied with the developers kit. The code generated
by the compiler when accessing a word field from an array of structure
pointers appears to be bad. [The address calculation is performed in
16 bits, not 32]. Can anyone help ?

```
Along lines of
  struct {int a,b} *tabptr[100];
  tabptr[i]->a = 12; gives wrong code
Jon

> At $400, the ST might make a nice printer buffer for my Amiga....

   Why doesn't Commodore just raise their prices up to the $10,000 range,
and then people will buy Amigas instead of PC-ATs?  One reason may be that
not everyone is convinced that list price == real value.  Furthermore, not
everyone buys the most valuable system - sometimes one can't afford it, and
has to settle for an affordable system.  (As for me I'm buying a Sun 3 with
```

hard disk server instead of a 520ST or Amiga -- at least that's what I'ld like to do, if I had the money to do it.)

Seriously - the major *real* problem is that Atari could disrupt their dealer support network, making the 520ST less attractive to serious buyers. Of course since most developer/serious/hacker-type buyers seem to be already buying via mail - there may be little support present anyway, and then that loss will not make any difference. The added volume of sales of the ST would probably make developers more interested, though.

*** REPLACE THIS LINE WITH YOUR MESSAGE ***

Until there is a net.micro.atari.source I will post ALL sources
for the 520ST to net.micro.atari and net.sources

Also it is not uncommon for binarys to be placed in the public domain !!!!!!

For he who can't help but think of a <$400 computer as being a toy:

You must have thought the original Atari 800 was one mean number cruncher
since it was priced over (?) $1000. I'm sure glad I bought mine when the
price was still up to $500, or else I would have just gotten a toy.
By the way, I didn't know the hospital ward you're in had access to
electronic mail...

Unfortunately, its worse than ST's being sold in K-MART stores. They
are being sold by JS&A mail order. These are the people that also
sell ionizers and other such nonsense. Price for the CPU with mouse is
299. Color monitor 399 mono monitor 199 disk drive 199. I saw the ad
in the Jan 13 Newsweek. I think that this is an absoulutely stupid
marketing move on Atari's part. I had faith in Mr T., but now I think
the 5 year old down the block has more marketing sense than he does.
I don't know how any future machines (including the 32 bit work stations

announced in the Electronic Engineering times) will get any respect
at all. If I was the head of Commadore I couldn't ask for a better
break at this time. Time will tell what impact this has on us ST owners.
We can always hope for good software from Europe where the ST seems to
get more respect.

>A friend of mine is looking for an 850 interface module. Anyone have an
>extra they will part with??
>

   No, but I've been looking for one for awhile, and am finding it extremely
difficult (and for those of you who have seen them advertised in Atari
mags, I've called them all: no dice). However, it looks like there may be
an alternative sometime (soon?). In the inside back cover of the December '85
Analog Computing, there's an ad from ICD, Inc. for what they call the
P:R:Connection. It reportedly is totally compatible with software for the
850, and can be used with all 8-bit Atari machines. I called them
mid-November, got the retail price ($79.95), confirmed that it would work
with a 1200XL, and was told it would start shipping to retailers Dec. 15.
I also called them December 15, when they stated that it would be out by
mid-January. I plan on calling them once more in a week or so. If it's not
out, I'll let 'em know they lost a potential customer.
  If you want to get the scoop yourself, or want to encourage them to get the
thing out the door (if they haven't already), they are:

   ICD, Inc.

   1220 Rock Street, Suite 310
   Rockford, IL 61101-1437
   815/229-2999

As noted in the subject line, today's WSJ-BB said that Atari will begin shipping
the 1040ST to computer stores today. Atari will also introduce a 20 Meg hard
disk. No prices were quoted for either.

I would assume that the rest of Erik's info is in the ballpark. I have heard no
mention of any ST the other than the 520, 1040 and the rumored "TT".

The humor of it all is that Commodore Amiga
was in a real awkward price position in the market, and now they stand alone
as the mid-priced REAL Computer (I can't help but think of a $400 computer
as anything but a TOY - albeit a great toy).

It is a shame to see intelligent people judging computers only by their price
tags. I would think that the price reduction would increase the value of the
520ST, not decrase it.

Jack Bicer

>
>   R.T Bradstrum

On the contrary, I think that Mr T's "error" is not in undercutting
the computer stores by going to KMart and mailorder,
but in bothering with the computer stores in the first place.
Computer stores are essentially useless institutions whose salespeople
know what we'd learn in an hour of pushing the mouse and reading
the manuals (horrors!).
I'd rather read Netnews, see a demo at a club meeting or a friend's
house, then buy the pieces of the system in sealed boxes from
Toys R Us or thru the mail. Really.

However, Mr Bradstrum does hint at a valid point: the IMAGE,
or "respect" that a machine acquires. This WOULD be helped by
the potted-palm computer stores. We netnews sophisticates
must remember that the unwashed masses respond strongly to
image. The Atari 800 and Radio Shack COlor COmputer were
hurt just by their brand names, while a dull 8088 PC was sold
by 3 little letters. On the other hand, I don't think the C64
got hurt by moving from computer stores to toy stores.
Politicians would rather have votes than respect, and Mr T
will gladly trade respect for lots more sales.
So should software developers (think about it...).
     mike k

PS: JS & A's monitor prices are $50 higher than my
guesstimates in yesterday's posting!

As I understand it (COMPUTE! Oct. 1985 article) CPM-68K is not "emulated" --
it IS the basic operating system, and the GEM "Desktop" user interface runs
on top of it. Why they don't give the owner access to CPM-68K free instead

of charging $300 bucks more for "special software and documentation" I don't quite understand if COMPUTE!'s description of the situation is accurate, but I am sure the hacker community will save us all the $300 by providing the necessary information in the public domain.

By the way, does anybody know if the K-Mart Special will include disk drive? Mouse? RS-232 and Centronics ports? RGB or composite monitor outputs? I heard that it would include a TV modulator, which makes me think maybe not the normal monitor outputs (although the little 800XL has both composite and RF outputs).

I don't have an 850 inteface, but if he needs it for just serial communication,
then there is a fairly inexpensive alternative. He can buy RVERTER. It
lets you talk at 300 or 1200 baud, works with most modems and comes with
the communications program on disk. I use it and recommend it highly.
The cost is about $40 from mailorder(look in the back of magazines).
It does not provide a parallel interface though.

I totally aggree. I think that Jack Tramiel should make the price of the ST
$400 higher than Amiga's, then it's going to sell like pancakes and be a
much more powerful computer. :-)
I bought my Atari 800 for $900 several years ago and it's a lot better computer
than the $400 Atari 800 you could buy several years later. :-)

Someone filled in the blank on my comment about the bank selection
abilities of Action!. I suggested it might be 32k (there was a
question mark after that estimate) and Ray supplied the proper 8k
figure. He added that only 8k is in memory at once. This might
not be true. According to the documentation, if used in conjunction
with the DOS-XL (the advancement from OS/A+, also by OSS), there is
the possibility that you can access 4 of the 8k that the Action!
cart seems to occupy, reducing the total occupancy to a minimum
of 4k! (NOTE: I havn't TRIED this, just reporting the possibility...)

Does anyone know if DOS-XL is really required to do this trick?

I am trying to establish a Quick and Reilly account (through QUICKWAY)
on Compuserve using HomeTerm (part of Home-Pak) and an Atari 800XL.
Customer service at Quick and Reilly tells me the reason I cannot use my
new account is probably that HomeTerm sends a line feed along with every
CR.

Has anyone done this sucessfully with HomeTerm? Does anyone know how to
turn off the line feed if that is what is really happening? Has anyone
used a Quick and Reilly account on Compuserve using HomeTerm? Note:
everything else on Compuserve works fine.

Any information would be appreciated. My frustration level is rising.

                            Thanks,
                            -Brenda

The messages received from folks happy that they can now get to
the archives are very much appreciated. And there's even more.

Another directory has been created. <info-atari> contains all of
the message archives plus the program library. I can't
describe what's in there because I don't know, but the directory
listing follows.

```

I do not think so. Time and time again, majority turned out to be RIGHT, and those lonely voices were wrong. This may prove to be such a case.

> A serious concern -- that selling the ST in toy stores at
>toy store prices will lead to the overwhelming preponderance of
>ST software being toy software ..

Who writes the so-called "Toy Software" ?? Highschool hackers ?? Neighborhood cabbies, Aunt Gwendolyn ?? And why is it such a serious concern ??? Is there some sort of a class difference between programs written by those of us lucky enough to have VAXen spread out in our machine room, and those written by a highschool nerd in his basement C64 ?? Remember that highschool nerd who broke into Lawrence-Livermore Labs ?? Did you know the JOVE was originally written in Lincoln-Sudbury highschool ?? But you perhaps know that professional programmers could churn out just as much crap as any other non-professional programmer (such as the cabbie) with the difference that the former is probably more dangerous. If lotsa kids get their hands onto an ST instead of a retarded C64, I am sure we will see more imaginative stuff, not TOY SOFTWARE.

>

Ah.. this must be the standard "class" oriented thinking. If it does not cost you your left arm, and it is not sold by an obnoxious salesman, it cannot be all that good.

Think about it: your VT220 costs more than an atari ST.
and it is not even programmable. :-)

Are you sure you don't own a computer store? 8-)

It is better to sell something at a fair price than to bilk the public with
outrageous pricing such as exists with Apple stuff.
But if you really think a computer turns into a toy due to its pricing, I will
buy an ST at K-Mart for $400 and sell it to you for $700 and you will have a
'real computer' again.

And to be perfectly honest, I have absolutely no feelings for computer stores
one way or the other, if they go out of business, tough. I know they had no
feelings of sorrow when they tried to charge me $400.00 to upgrade my 16k pet
to 32k several years back. I did it myself for about $30.00.

If you want to subsidize computer stores, fine, but I don't, and given a choice,
I would rather subsidize a farmer.8-)

this is ray saying bye bye.

After only one evening of examining OSS's pascal I am
impressed.
1) The documentation is much clearer than Atari's own development
   kit and it flows logically.
2)It supports almost all GEM functions with some exceptions (redundant
  functions). Actually it allows access to even those functions if
  you have DRI assembler or C compiler.
3)The programming environment is integrated very nicely into the ST
  GEM. You do your compilation via a pull down menu. The compilation
  and linking process seems pretty fast.
4)Sections covered:
  + Gem Initialization and Exiting
  + Alert Boxes
  + Dialog Boxes
  + Predefined Dialog boxes
  + The menu bar
  + Window management
  + Window Text and Graphics
  + Mouse control
  + Event management routines
  + GEM messages
  + Miscellaneous routines

OSS Pascal allows seperate program module compilation for later linking.
So one is able to build libraries, etc.

The documentation comes in a bound book with ~250 pages of
info. The cost is around $80. I prefer to work in C but the elegance
of OSS programming environment will force me to work in Pascal.
I compiled four of the included programs and found the compilation
speed reasonably fast.

You can reach OSS at:
OSS can be reached at 1221 B Kentwood Avenue, San Jose CA 95129
408-446-3099
---
not affiliated in anyway with OSS

Also, why does a high price change a toy machine into a "serious" one?
I have great difficulty considering a machine which can't display
reasonable-quality text without flicker anything but a sophisticated
games machine.

Hello all,
Me and my friend,tried connecting the 1030Atari modem to my
Atari800(not the XL)we got everything right,soft loaded ect..
we dialed the main frame and the modem did not respond to the
computer tone...we tried it at my friends house,on the ATARI
800XL...and it worked there fine,any ideas?

Kurt Godden's comment about hospital wards is the latest of a
series of childish and immature messages which have plagued the
INFO-ATARI list of late.

This is very reminiscant of the Atari user's groups of the
early 80's, which insisted Atari was doing everything splendidly

and the few people who argued otherwise were lonely voices in the wilderness.

A serious concern -- that selling the ST in toy stores at toy store prices will lead to the overwhelming preponderance of ST software being toy software -- is trivialized by suggesting that anybody who dares to have such concerns must be in a mental hospital. If you want to advertise the Amiga I can't think of a better way than the current cat-fighting.

There is a difference between a cheap and an inexpensive computer. The ST was promoted as being inexpensive, but it sure looks like it really is just another cheap computer.

I have IDRIS. It does have fork(). It can run more than one process in memory
at once and usually does but after a fork it runs the parent and child in the
same space by swapping. Of course, as soon as you do an exec (most of the time
right away) it gives you a new space and the swapping stops. This is entirely
practical and works just fine. I see no reason why a similar system couldn't
work on the ST - but it couldn't be SysV or 4.2 because some of the calls
require memory mapping, e.g. realloc().

There are several ways you can build and market a computer to replace (or compete with) some other computer:
(1) build a better machine and charge more
(2) build a better machine and charge the same
(3) build a better machine and charge less
(4) build an equivalent machine and charge less
(5) build an inferior machine and charge less

Many people are confusing Atari's actions with strategy (3). The problem is that you fail to consider medium-to-long term market forces. In general, the industry has provided a 30% price/performance increase every 2 years. In the micro industry, it's closer to 30% every year. Another way of looking at it is either an order of magnitude price decrease in 5 years, or an order of magnitude performance increase in the same period of time, or a combination of both.

Atari's marketing strategy leaves them with no way to maintain the curve they have set. The value is almost guaranteed to go down with little or no significant equipment enhancements. This is fine for throwaway computers (a.k.a. toy computers), but not for serious computers. A software developer writing a serious application is going to want the machine to be on the market for some time so his software product would be saleable.

> >it?

Another reason (aside from the piracy issue) why you cannot have ACTION!
(or, for that matter, BASIC XL/XE or MAC/65 with DDT) on disk is that these
are the only cartridges making use of a technique called BANKSWITCHING.
They are actually 16K carts taking up only 8K of address space. If you use
OSS's DOS XL, DOS will use the RAM "hidden" by the cart for even more
program memory. The capability to use this feature is another indication of
the fabulous design and forethought that went into these little 8 bitters.
I just got another one of them! The newest incarnation (130XE) carries on
the proud tradition with a nicely thought out approach to bank switching
its 128K RAM and supporting its parallel bus.

By the way, you can obtain a runtime library to make your action programs
independent of the cart, or modifiy the IO library to do program
development for the C64 or Apple (you better know the respective OS's to do
that...).

The simplest way is to read the value of the 200 Hz system timer contained in location 4BA -- The hitch Hikers guide says 4BC but that is a misprint. It has to be done in super mode otherwise you get mushrooms. Here is a example

```
long ticks;
long *_hz200 = 0x000004ba;

read_ticks()
{
     ticks = *_hz200;
}

main()
{
......
     /* Call read_ticks in super mode - this def if missing  in
     osbind.h */
     xbios(38,read_ticks);
     /* ticks now has the value of the 200 Hz timer */
}
```

You could also use the Xbtimer() xbios call with timer a, but I have'nt gotten it to work correctly as yet (I had posted a query a couple of days back, but still have no answer).

Some people over here have been hacking midi code too. One of their experiences was that incresing the size of the midi receive buffer helps a lot too in keeping up with some of the Yahama equipment that send status bytes every 200 ms (I think). this can be done by using the Iorec() xbios call. Hope this helps.

Hitting a lot is ^c's does it for me. If you simply hold down ^C it
will not do it. The latest version of sttalk has the capability to
send breaks. Hit CTRL-<clr-home> to send a break.

I have written a simple function which accesses the 200 Hz timer tick, unfortunately it is the highest resolution timer that I could find. [If anyone knows of a 1 ms timer I would like to hear about it.]

This function requires that your program include osbind.h (for the Super() function); which requires that you include osbind.o when you link your program. Note that the address pointed to in the "Hitchhiker's Guide to the BIOS" is not correct. I suffered greatly over this until I started poking around using SID. The address is correct in the BIOS listings.

Lee Mendoza

```
/* timer.h -- returns a longword containing the number of milliseconds since
 *            booting, with a resolution of 5 ms.
 *
 * Written by Lee Mendoza
 *
 */

long timer()
{
  long stack, time, *timer;

  timer = 0x4ba;              /* _hz_200:  200 Hz system timer tick */
  stack = 0;                  /* null the stack pointer */

  stack = Super(stack);       /* enter supervisor mode, save the stack */
  time = *timer;              /* get 5 ms timer tick */
  stack = Super(stack);       /* exit supervisor mode, restore the stack */
```

```
  time = 5*time;                /* calculate the time... */
  return(time);                 /* and return it to the caller */
}
```

Here in Germany a CP/M-80 Emulator is distributet free (!!!) by
the ATARI dealers. Nice thing. Wordstar and Turbo ran fine (with
some screen output patches). Speed: about 2 MHz,
thats the speed of the standard Microsoft Z80-Card in the Apple.
Atari Germany sent the program to her dealers, mentioning that
it can be given away to every 520ST owner. Availibility: since
November !!!!!

>...
>We can always hope for good software from Europe where the ST seems to
>get more respect.

I think you are right, especially when reading news on the net. Here in
Europe are no diskussions like that in the USA "520ST vs. AMIGA" or
"ATARI ST vs. C128". Silly things. Here in Germany the 520ST sells fine
(no Amiga until Spring/Summer 86) and many professional program

packages (wordprocessors, databases, an specialised commercial software
for the german market) are availible. Go on diskussing, we will have fun
in the meantime (:-)). Here at the University of Dortmund we bought only
in November and December last year about 30 ST's (all with 1 MB) and they
work really fine and they are in great demand.

    Hello all,
    Me and my friend,tried connecting the 1030Atari modem to my
    Atari800(not the XL)we got everything right,soft loaded ect..
    we dialed the main frame and the modem did not respond to the
    computer tone...we tried it at my friends house,on the ATARI
    800XL...and it worked there fine,any ideas?

CES - THE FIRST DAY
By Jack Powell

Las Vegas, NV - The Consumer Electronics Show! Only six weeks have passed since ANTIC attended the massive COMDEX in Las Vegas (just enough time for three holidays, two turkeys and an armload of gifts). And now, here we are - back in "Sin City" for anequally massive CES.

FAMILY OF ATARI PRODUCTS

Atari Corp. displayed their "family of Atari products" in a huge booth with over 81 monitors featuring videotapes of everything from Dig Dug on the 2600 video machine to Star Raiders on the 520 ST. Whereas Atari had displayed primarily ST software support at COMDEX - a show primarily for the high end of the computer industry - their exhibit here at CES is focused on the mass-market; the K-Marts and the Toys-R-Us outlets.

The Atari exhibit is three huge walls of monitors. Looking from left to right, while standing in the middle of the purple corral, one first sees 12 monitors displaying 2600 games, including Pole Position, Stargate, Moon Patrol, and Joust. The 2600 has been

redesigned as a smaller unit and will sell for $39.95. Release date is expected to be February 1st.

To the right of the 2600 screens are twelve 7800 screens. The 7800 video game machine was developed by the previous Atari company and exhibited at the June 1984 CES just weeks before Jack Tramiel bought Atari and temporarily squelched the project. The machine features excellent color graphics (due to the "Maria" graphics coprocessor) that appear tobe slightly better than the 8- bit computer line, but not quite up to coin-op (or ST standards. Maria has exceptional bit-block transfer capabilities.

At CES, the 7800 was displaying crisper and faster versions of the same games as the 2600, plus Pacman, Xevious, Asteroids, Food Fight, Robotron, Galaga, Centipede, and the first two Lucasfilm games: Rescue at Fractalus and Ball Blazer. Although Atari told us the e achine was ready to market immediately, they have not yet settled upon a price. The unit should sell for between $69.95 and $79.95. There were an additional 48 monitors showing videotapes of mostly ST software coming from third party developers. Unlike the COMDEX exhibit, where Atari was surrounded by third party ST developers (using Atari's equipment), at CES, the third party support was represented on cycling video displays with company title credits.

Atari was also displaying the "Boink" comparison of bouncing balls on the three 68000 machines -the Macintosh, Amiga and 520ST. Over in the 8-bit area, however, Atari was delighted to have just received a newBoink demo for the 130XE from XEVIOUS - a software store andST development company fromSeattle, which had beenresponsible for the previous 8 -bit Boink.

The latest Boink features a spectacular, spinning 3-D fuji in place of the familiar ball. Additionally, one side of the fuji displays the well-known scrolling rainbow. Very impressive. You can find it in DL4 of the 8-bit SIG*Atari by or before January 14th.

STAR RAIDERS

Star Raiders, the classic 8-bit arcade game, is being adapted by Atari for the ST by programmer Rob Zdybel. A demonstration of the ST version was lighting up a monitor in the Atari area. The game is about one-third complete, and there's no warp drive yet, so we can't report on that particular effect - sorry. But the ships are displayed with solid modeling rather than wire-frame. And, currently, the most impressive part of the demo is the control panel on the lower half of the screen. It's a very detailed graphics display reminiscent of the control panel in Koronos Rift. Atari has no price yet on this software, which it hopes to get to market by early March.

Meanwhile, on the 130XE, Atari was showing the eong-awaited Star Raiders II. The game looks remarkably similar to a previously un- released arcader called "TheLast Starfighter", which some insiders may have seen about a year ago in a beta version.

But Atari has done a lot of work on the game to improve its playability and it look more like a sequel to Star Raiders. The star field now moves inresponse to your joystick giving the illusion of spacial dogfighting. It's moredifficult to lock in on your destination planet and the orbiting algorithm has been fixed so you

can slow yourself down by pulling on the joystick - but you can nolonger go backwards. This makes bombing runs a lot more of a challenge. Other added goodies include shields, space stations and a tactical display. Star Raiders II should be in the stores very soon at a price of $39.95.

Atari displayed no new hardware at this CES. The 1040 ST is not on display, and the rumored 80-column card and 3 1/2-inch drives for the 8- bit machines were also absent. According to Atari spokesmen, both the 80-column interface and the smaller drives will be announced at the Hanover Fair in Germany.

When the drives are shown, they are expected to be single-sided, holding 325K - formatted. The access time on the 3 1/2-inchers will beabout twice as fast and DOS 2.0S and 2.5 files may be "upwardly" ported to the new drives but you won't be able to port files in the other direction.

Atari will be marketing a packaged 130XEwhich includes 1050 disk drive, 1027 printer, and bundled software. The "starter package" will sell for $399, and the software be Silent Butler, Star Raiders, Music Painter, Paint,and AtariWriter. The package will become available February 1st.

THE 1040 ST

Although Atari was not displaying the 1040, they did officially announce its existence. Photos reveal a machine identical to the 520ST, with the exceptions -as previously reported by ANTIC - that the disk drive slot is where the mouse and joystick ports once were, and the ports have been moved to the right-front under the keyboard. The depth of the back section is about 1 1/2-inches deeper than the width of the current drive slots. Also, it appears as if there is a slightly different eject mechanism in the drive.

The new machine, featuring one megabyte of RAMand built-in double sided disk drive, will sell for $999.95 (monochrome) or $1199.95 (color).

Atari has slated the 1040ST for exclusive distribution to "authorized" computer dealers and said the520ST will be given wider distribution "beyond computer specialty dealers." The 520ST will be aimed toward the consumer who wants to trade up from an 8-bit to a 16-bit.

Atari also announced the availability "next month" of a 20 megabyte, 5 1/4-inch hard disk peripheral - the SHD -204. No other details were provided on the eagerly awaited peripheral.

Once again, Atari is "packing them in." Every time we stopped by their exhibition area the crowds were thick{ ST Software developers are scattered throughout several CES exhibition halls. Over the next four days ANTIC will bring you the latest detailsand keep you up to date on the products and the press releases.

Stay tuned.

JANUARY 10, 1986

CES - THE SECOND DAY:PRODUCTS

By Jack Powell

Las Vegas, NV - Though most CES insiders agree this year's Vegas show has far fewer software exhibitors, a thorough search reveals a wealth of Atari related goodies at this giant, electronic toy store.

Many developers, having decided the high cost of booth space is not worth the exposure, are displaying their wares in hospitality suites scattered throughout this desert city, while still others simply wander the fair and show off their wares at other's booths.

In one hospitality suite, Datasoft was displaying the recent 8-bit products, Goonies, Zorro, and Alternate Realities. The latter fantasy role-playing epic is currently being adapted for the ST by a team of programmers led by John Butrovich. Philip Price, the game's original author, will act as creative consultant.

The ST version of AR will take advantage of the ST's greater power and RAM capacity to include many concepts Price had always wanted in the game. There will be magic spells, for example, and you will be able to get a job and earn money - as well as meet others and earn their admiration... or their hatred.

The ST AR was started two months ago and Activision hopes to have the first disk - The City - to market by Christmas of 1986. The second disk of AR will be The Dungeon. It is also currently under development for both the ST as well as the 8-bit machines. No release date has yet been set but both versions will debut simultaneously.

A third disk, The Arena, is currently being brainstormed. Arena will allow users to pit two developed characters against each other.

Batteries Included was demonstrating their fine collection of Atari software. The Isgur Portfolio System - a high end financial package - has been released for the IBM.

According to BI, it will be available for the ST sometime int 1986.

BI is also developing a full-scale telecommunications program called I*S talk, and a time management and billing system called I*S Time. These too will become available for the ST in 1986.

Batteries also announced a special purchase policy for educational institutions. For every three or more BI packages purchased, BI will throw in an equal number of the same title for $10. Not bad

Soniture, Inc. showed off the Space Pen, a three- dimensioinal light pen, currently available for the 8- bit computers, and soon available for the ST. Space Pen requires its own software to take advantage of the third axis, but it will take the place of a touch tablet on two -dimensional software products. Space Pen is $150 on the 8-bits, and $175 on the ST.

Compute! Publications has a new book: The ST Programmer's Guide. The 356 page volume retails for $16.95 and includes an introduction to ST BASIC, plus explanations of the BASIC keywords. There is also a section on Logo concepts and a rundown of the Logo primitives.

In back of the Programmer's Guide is an explanation of the GEM VDI calls and how to access them from BASIC. Although GEM theory is explained, there is no listing of AES calls and no explanation of C access to either VDI or AES.

Microprose is showing a new 8-bit strategy simulation called Conflict in Vietnam, written by Sid Meier and Ed Bevers. The game, which is due in early March, is similar to the company's Crusade in

Europe or Decision in the Desert. There are five battle scenarios you can choose among, which are based upon five decisive battles of the 60's "non-war".

Microprose was also demonstrating Silent Service, for the ST. Programmed by Silas Warner - who did Castle Wolfenstein - the game is expected to hit the dealer's shelves in late March.

PrintMaster, a printer utility similar to Print Shop, is being developed for the ST by a company called Unison World. The product, which is currently available on the IBM PC and Commodore 64, was not being shown at CES.

HELP FOR THE UPRINT

Digital Devices makes a printer interface for the 8- bit Atari called Uprint. The initial releases of the product had a few bugs in it and the company originally established a replacement policy which they now feel is unfair.

They have asked ANTIC to pass the word that all owners of the earlier Uprint (you can tell the earlier models by the existence of a copy switch) may receive a free exchange. Simply return your original unit along with $6 for shipping.

Jim Schwaller of Extended Software was showing Disk Library, an ST file cataloging utility currently available for $39.95. Extended Software is also related to Classic Image Software which is planning the release of a marble-rolling game for the ST called Diablo, due out in late March. Classic Image is, somehow, related to Classic Covers which makes plastic dust covers for all Atari peripherals...right down to the mouse.

Accolade announced a February release date of Sundog. The announcement was made from a hospitality suite and, though Accolade was not demonstrating the program on the ST, ANTIC has seen it and can attest to its superior graphics.

ABACUS Publishing displayed their newest ST books. ST Internals is all about the ports and the BIOS and includes a listing of BIOS system calls. ABACAS also has a 68000 machine language book for the ST. Both these books are currently available. Coming January 27th will be their GEM Programmer's Reference book featuring the VDI and AES calls. All three books retail for $19.95.

XETEC, Inc. is developing a CAD package for architectural drawing. The ST program, which was demo-ing, will be available in the second quarter at a price no higher than $99.95.

BACK AT ATARI

Meanwhile, back at the plum-colored Atari corral, Charles Andrews demonstrated his home-brewed 320XE. The machine has been upgraded to contain 192K RAM over the standard 130XE's RAM. It is completely compatible with any XE software and enables such niceties as two RAMdisks plus one floppy - without touching the 130XE's memory.

Atari was interested in the idea, and asked Andrews to display his upgrade machine for awhile to get reaction from the CES crowd. If any of you want to see this product in the Atari lineup, contact John Scruch at Atari.

Bill Wilkinson of O.S.S. premiered their Personal Pascal for the ST. It looks like another winning language from this company.

Version 1.0 boots to a familiar GEM menu bar with drop-down menus for editing, compiling and linking. Default options for the compiler

and linker may also be adjusted from here then optionally saved to disk.

Compiler options, for example, include pause on errors, chain to linker, debugging options, and GEM or TOS structure for final output code.

The editor is a command-based text editor that has a full Help screen for all commands, and a cut and paste function very similar to the ACTION! editor. We were particularly impressed with the fact that the editor also has auto-indent. A feature sorely lacking from all ST program editors up to this point.

O.S.S. has designed their own custom calls to access both GEM AES and VDI. Not satisfied with the original design, they rolled up their sleeves and made a few changes. To open a workstation, for example, you need only one call: InitGem. That's it!

Documentation consists of a very full-looking, 284- page paper-bound book. The language is currently being shipped and retails for $74.95.

MIDI MARVELS

The Casio exhibit at CES is a sprawling display of synthesizers, watches and other electronic marvels. In one corner ANTIC found Micro- W, a company with a novel approach to MIDI software. Q.R.S. Music Disks are player piano rolls translated to MIDI song drivers for the ST.

The company discovered the original Q.R.S. player piano company was still making the rolls and set about converting all that music to synthesizer code. As a result, for $19.95 you can buy a disk of Scott Joplin rags. Or, how about some Gershwin? An entire catalog of disks is expected to be available soon.

Just pump 42nd Street into your synthesizer and then alter it to suit your fancy.

Also, for the MIDI crowd, Hybrid Arts - creators of the MIDI Track-3 for the 8- bit machines - stopped by the ANTIC booth to discuss their latest MIDI software for the ST. DX-Droid, is a patch librarian/editor and the first MIDI product to use a form of artificial intelligence. DX- Droid can actually program your Yamaha DX-7 for you. Programming the DX-7 is said to be so complex, there are people who are paid to do it.

Hybrid Arts will also be releasing a sequencing program called MIDI Track ST, which will be able to read and write SMPTE time code. It can also record and play back system exclusive data. (Those last two sentences are for you MIDI freaks out there.)

MIDI Track ST will be available in both a "professional" and a "consumer" version. DX-Droid will be available in February.

No release date has been set for MIDI Track ST.

For those of you with a strong interest in MIDI's, you might want to log onto the Hybrid Arts MIDI BBS at (213) 826-4288.

>system? Am I missing the point entirely? (Perhaps PC UNIX's
>fork() does NOT act like real UNIX.)
>
>   Ranjit Bhatnagar

We have several Unix systems (not Unix-like) running on the PC. They are
VENIX (Unix V-7), VENIX-V (Unix System V), and PCIX (Unix system 3). These
are all AT&T licensed Unix's and work the same as one other systems (we
also have a CT Megaframe running UNIX System-V, and we port back and forth
all the time).
     However....
     These Unix's DO have the use of limitted MMU capability. The 8086
family has a (disgusting) memory management scheme which uses base registers.
All programs which use less than 64K dataspace are relocatable by simply
changing the contents of the base registers. This is better than absolute
addressing in that even pointers are relocated. It also adds the very
severe limitation of 64K data spaces.
     I agree tha`i MMU's would be nice on the ST. However, it is
possible to make a UNIX (or something very close to it) without
MMU's.

You're right - it's not difficult.

I have done this myself, so rather than just reply with the appropriate
routine, I draw attention to the routine hz200() in the following program.
It is a MIDI recorder - it listens to what is being played, can store it on
disk, and play it back. I hacked it together in an afternoon, so it's not
earth-shattering stuff. It only listens on one channel, and ignores all
but note information. It does preserve velocity information, and was tested
on a Yamaha DX7. If anyone does improve this, I would appreciate seeing the
source code.

PS - can anyone spot the deliberate mistake?

/* mr.c */

```
/* Nigel Roles 1986 */

#include "osbind.h"

#define MIDI 3
#define CON 2
#define GM (Bconin(MIDI)&0xff)

struct event {
     int delay;
     char cmd[3];
};

struct event *buffer;

int empty=1;
long bc;
long memsize;
long bmax;

long hz200()
{
     register long save_ssp=Super(0L);
     register long uhz200= *(long *)0x4ba;
     Super(save_ssp);
     return uhz200;
}

record()
{
     register struct event *bp;
     long now,then;
     printf("Recording (any key to stop):\n");
     while (Bconstat(MIDI))
          Bconin(MIDI);
     then=0;

All right, I suppose this is a flame. I've been criticized before for what
I'm about to say, but I can't hold this one any longer.

[Re: Amiga Text]
>I have great difficulty considering a machine which can't display
>reasonable-quality text without flicker anything but a sophisticated
>games machine.

I have seen text on both the 1070 and 1080 monitors, which most Amiga owners
use. It is entirely stable in 80x25 (640x200) mode, and is a joy to read.
I personally prefer amber on black text; this is particularly readable.

Amiga text, while certainly not superior to IBM Monochrome text on the IBM green phosphor monitor, is easily in the same league. And Amiga text is far more stable, clear, and readable than text on the IBM color monitor, the Macintosh, or almost any other micro-computer level color monitor I've seen. I have not seen 520ST monochrome text; I hear it's very sharp. But please don't criticize Amiga text until you've seen it.

I have completely struck out trying to use Kermit from my Atari to a UNIX system. Any suggestions would be appreciated.

The Atari Kermit is contained in Chameleon. For TAC transparency I used @I N. I found that the @B O S and @B I S sequence left me with a hung terminal.

Kermit send from UNIX to Atari worked until the Atari did disk output. Apparently the UNIX Kermit just kept on sending. When the Atari returned from outputting, I saw what must have been Kermit packets on the screen. Eventually, the UNIX Kermit timed out.

Optomistically, I tried sending from the Atari to UNIX. The resultant file was almost empty.

Sincerely,

- Marshall D. Abrams, phone: (703) 883-6938

The problem with posting sources is that many sources are compiler
specific, and many people don't want to muck with the code to get it to
compile. And a lot of people don't even have the compilers. An
equitable solution might be to post BOTH sources and binaries, but you
run into the problem of transmission costs. To make the code usable for
the largest number of people, you have to post binaries (which are
smaller) and posting sources should be up to the discretion of the
poster.

Here is a digital clock desk accessory. It is quite simple - a window
with no contents and a title which displays the time.

Enjoy!

Jan Gray Looking Glass Software, Waterloo, Ont.   (519) 884-7473

its more than just that, there is a certain childishness about it,
kind of a 'ill let you look at it but its mine and you can't have
it' attitude that i find annoying. also it shows a lack of co
operation, why are we posting a few binaries while net.micro.amiga
runnith over with sources compared to us.

If they were going to give you two disks, it would probably be easier for
them to give you two copies of the system disk.

Actually, the reason I wanted to compile STComm was to use a 1200 baud modem I've got, which is just appalling using ST Talk. Believe it or not, the local store is still selling this garbage. It owrks for xmodem, but everybody but the computer store down the street seems to know that the VT52 aspects don't work on, for instance, vi. And I just wasted $40 on a program called typesetter ST. It now lies on the floor. That's the last time I get pressurised into buying garbage like that. From now on, I reserve the right to walk out of a computer store without buying anything!!!

Now my real reason for this note is to expound on my theory about what is wrong with the ST Comm. Well, nothing, except that pass 1 (I think) of the DRI C compiler gives a warning about multiply defined cases. You will see clearly from the following excerpts why. DRI has 16-bit ints, whereas Hippo has 32-bit ints. Hence Hippo thinks F3, F2 etc. are different, and DRI thinks they are all 0. Clearly the solution is to make c a longword. One of the problems with C is that it cannot be machine-independent. If every program refuses to use any larger integer than 65k, then that is resources wasted, but the alternative is non-portability. The real solution is, of course, to use

```
#define WORD short
#define LONGWORD double
```

or something similar, and then for different compilers, adjustments can be made at teh beginning of the program. I haven't checked the rest of the program. Nor have I run it with the corrected type for "c".

While I'm on the topic of use of the top portion of a longword, someone posted a warning a while ago that use of the top byte of addresses was dangerous because it made the code non-upwardly-compatible with later 68k chips. If the ST is ever going to use a 68020 chip, it's going to need a major overhaul in the OS, because the top byte is used with wild abandon!!!

And now this....

```
#define F10 0x440000
#define F1 0x3B0000
#define F2 0x3C0000
#define F3 0x3D0000

###### about 150 lines of code #########

put_serial()
{
unsigned int c;
```

```
int wait;
short go_on,n,st;
char name[14];

inv_on();
printf("\n**** F10 = exit to MAIN MENU ****\n");
inv_off();

ctr = 0;
st  = OFF;
wait = 0;
cnt = 0;
go_on = 1;

while (go_on == 1)
{
 while ((n = conis()) < 0)    /* GET CHAR INPUT WITHOUT ECHO */
 {                 /* SCREEN */
     c = necin();
     switch (c)
     {
     case F3 : dsave_on();  /* SAVE TO DISK */
                break;
     case F2 : transmit();    /* TRANSMIT FILE */
                break;
     case F1 : psave_on(); /* SAVE FOR PRINTER */
                break;
     case F10: go_on = 0; /* EXIT TO MAIN MENU */
                if (psave == ON || dsave == ON)
                   dump();
                break;
     case HELP : help();
                   break;
     default : auxout(c);   /* OUTPUT TO SERIAL PORT */
     }
}
```

simply hundreds more lines of code

The second, third, fourth and fifth case statements are flagged as multiply defining a switch. This is because they all look like 0 to the compiler. Enough said. Most readers will either find this utterly trivial or incomprehensible. I hope someone out there finds it useful.

But the moral of the story, folks, is that you must find some way of assuring either portability or ease of modification. This rotten C language is so painful to read that no one really wants to go through your program to find out how the compiler is going to misinterpret your code.
zzzzzzzzzzzzzzzzzzzzzzzzzzz ....ak. The person who requested me to post this explanation is not responsible for the nonsense therein.
zzzzzzzzzzzzzzzzzzzzzzzzzzzz..............ak.

There seems to be some confusion as to the video outputs of the
520st. ALL of them have the following:

70hz Monochrome
Analog RGB
Provision for tv modulator.

If you have ever opened up your ST and seen the area where something
is missing, it is the video modulator that is missing. All Atari is
doing is putting in the modulator back into the ST.

You will still be able to use the 70hz monochrome monitor and the
Analog RGB monitors with the mass market ST.

  The hot-off-the-presses February Analog Computing magazine has a center spread of (all?) software available for the ST as of December 12. The listing includes each software company's address and 'phone number, and most entries include a list price. Support your Atari specific magazines!

I use a commodore color monitor for my computer and for my vcr by
utilizing the switch on the back of the monitor that switches between
the composite video hookups on the front of the monitor, and the
luminence/chroma hookups on the back of the monitor. Use a standard
shielded patch cord for the vcr hookup on the front. I use a seperate
amplifier for the audio so you may want to verify that the switch also
switches audio. The picture quality is excellent.

>

This is a really interesting theory. This guy says that as long as
the prices of the Atari and other companies are kept low, the
Amiga keeps a unique market position, which the others cannot
threat. So the only thing Atari has to do, is to raise the
price of their ST, to start the competition with the Amiga.

This is the most ridiculous marketing theory I ever heard. Of
course, the Amiga is more a business machine than the Atari, but
do you really think business people would buy a computer because
of it's higher price? If you think so, Commodore must have terrible

fears for Apple, 'cause the price of the Mac is about twice as
high as the Amiga and is even much more developed as a business
machine.

I think you must read some more books about 'Price and Quality' and
'Customers Behavior' before saying such heavy statements.

The present version of the ST (bundled) puts out a 70Hz monochrome signal,
and a 60Hz color (RGBA) signal (albeit only one at a time).

Since European EMI regulations for this type of equipment are much stricter
than the FCC's, this statement seems rather odd.

The current 520ST already scans at 60Hz for RGB. The 70Hz scan rate is
only used for the mono-chrome monitor. After looking at the mother board,
the only probable difference between current 520 and the one to be
introduced is the addition of an RF modulator. There is already a space for
one on the mother board.

Summary:

I have an Atari 20 meg developer's hard disk drive. I don't know how
close this one is to the final version that will come out. It's a
featureless, unmarked grey box with one red LED, a power switch, and
the hard disk connector.

Works great. It's almost as fast for compiling (using the development
kit) as a ramdisk. I have a 1 meg Atari, and I use a ramdisk to hold
the libraries. Personally, I wouldn't leave home without it.

OK. I -might- accept the preposition that a $400 price tag will make
many people -view- the ST as a toy computer. But the price has nothing
to do with actual performance. Unfortunately in cases like these it is
what people think that counts more than the facts.

The Amiga is (at least I am not afraid to say it) a better computer
that the ST. Just not enough to make up for the price difference.
Also, the software for each machine will probably maintain the hi/lo
cost split. My main concern is that by (even apparently, although not
actually) lowering the price on the ST, Tramiel is making the same
misteak that the 'old' Atari did.....give people the opportunity to
see a machine function as a toy and they will see it -ONLY- as a toy.

Enough of this. Does anyone have any interesting Action! programs (for
the 'older' computers) that they would be willing to post? Does the
person who posted "Harvey" a little bit ago realize that it does not
work quite right (my version at least....& I downloaded it twice to
make certain it wasn't a transfer error...the second time was with
JPs KERMIT in Action!.)?

>>[Only Atari would not number these pins consecutively!]

The numbering scheme used on the Atari Video Output connector is a standard 5 pin DIN plug with standard 5 pin DIN plug numbering so you can't blame Atari just the Germans.

Bill,

Re: using a Commodore 1702 Color Monitor as a monitor for a VCR

You shouldn't have any problem using plain RCA-RCA stereo cables, but
for optimum results you should use 75-ohm coaxial cable with RCA
terminations. For the audio portion of the signal you should stick with
the regular RCA phono lines unless the input requires something
different.

Jim Cooper

P.S. there is a videotech-info group

Bill,

I can't answer your question about the 800 XL but I can tell you that
you don't need all of the video signals that ATARI provides at the
connector to make a monitor work. All of the Atari computers deliver
Composite video on one of the five pins...I was not aware that they
might be machine dependent regarding the actual pin number. If someone
would want to use a monochrome monitor then a luminace only signal is
available.   ***The Pin numbers found on the 5-pin DIN connector have
been decided by the DIN (German Standards committee) so don't blame
ATARI for that one. An interesting ramification of the signals provided
by the 130XE is that a cheap RGB decoder could be built to derive the
component colors from the combination of composite luminance and
composite chrominance. I haven't fully investigated this yet but you
would need a sync stripping circuit, a couple of band pass filters to
separate the colors and maybe a few delay lines.   RCA makes a few
interesting IC's (CA3130--33) that take luminance and chroma signals an
turn them into R-Y, B-Y, and G-Y where Y is the luminance portion.
Those chips are designed for decoding broadcast signals inside your TV

set. Beyond that you will need to then transcode the R-Y,etc. (You
don't need the G-Y) signal into RGB for RGB monitors. As I actually get
into doing this processing I will post a more coherent description to
the net. This is the only way to get RGB out of an atari since the NTSC
composite video is computed a a composite signal.

I think $200 is a fair price. It took me from 4:00PM to 1:00AM to upgrade
and then another few hours nailing down loose ends (for example the mem
controller worked loose and I had to open up the box and reseat the chip).

I built a box about 12"x12"x3" which the monitor sits on. There is
plenty of space inside the box to house the power supplies. The setup
looks neat as a pin - there are almost no wires visible.

I have hooked my 1702 up to my VCR. Just use the audio and video inputs on the front on the monitor. All you need to do is hook the video output of the VCR to the composite input on the 1702 and hook the audio output to the audio in on the 1702.

Make sure you flip the input selector switch on the 1702 to the "composite" setting.

All ST's can use 60-Hz color monitors. The color monitor from ATARI is one.
Only the monochrome monitor is 70 Hz. That way the interlaced refresh is
done quickly enough to hide the first scan fade (causes flicker).

There is also a public domain XLISP and PROLOG (built on top of it).
Also, Dragon has released a demo version of their FORTH which I belive
does everything the full blown FORTH does except file transfer. I have
found that demo very useful - I have learned to program in FORTH using
it and I have been able to judge the speed of FORTH through benchmark
programs. Incidentally, I have found that FORTH is about 100 times faster
than ST BASIC. For example, the following program computes the 26th
fibonacci number in 25 seconds: (recursive program - for benchmark)

```
: FIB 0 SWAP -1 * SWAP BEGIN SWAP FIRST SEC OVER 0 = UNTIL SWAP DROP ;
: FIRST BEGIN 1+ DUP 1+ DUP -3 > UNTIL ;
: SEC + -1 * OVER 0 > IF BEGIN + OVER 0 > NOT UNTIL THEN ;
```

This example also helped convince me that I should not be programming in
FORTH. Incidentally, if anyone has a less cumbersome way to write a
FORTH program for fibonacci please send it to me. (I know there is a
fast iterative solution to fibonacci - this is uninteresting as a benchmark -
I would like to know of a better recursive solution - what I have done above
is use the sign bit to indicate whether search is proceeding to the "left"
or to the "right". Surely there is a better way - what would happen if
there were a middle son to be expanded? Would I have to use another stack
word to save the "return address"?)

I have a series of introductory articles explaining what Amateur Packet Radio is all about, and would be glad to forward copies to interested parties.

For those who don't know, the ham packet network is well established along the East and West Coasts, and is growing inland until it will meet in the next few years. Meanwhile there is some degree of HF ("shortwave") gateway service on 20 Meters between the two subnets. There is even the possibility of links to Europe either via HF gateways or via Amateur Radio satellites. Bulletin Board systems abound, and the neat thing is there are no phone bills!

All this is not particularly Atari-related, except that I am an Atari owner and a ham radio operator (I am careful not to shorten this to just "ham"), and am planning to put my 800XL on the air as a packet station in the near future. I would be pleased to hear from anyone who has done so or is also planning it. At present I am leaning toward doing my own software implementation rather than buying the commercial interface board that is available with an RS-232 serial port. It seems the Atari internal tone generators are more than adequate for sending 1200-baud FSK in software, and the receive interface takes only about 8 chips.

Atari fans, please consider this a pitch for getting into ham radio as a major enhancement of the computer hobby. The ham community stands ready to give you lots of help and encouragement in getting through the not-so-difficult license exam hurdle.

>   Bryan DeLaney

Good, but we need 60Hz monochrome (WITHOUT the 3.58 MC color
subcarrier).

Will all these options be on the Preferences screen? Hope so.
     mike k

~~~~~~~~~~~~~~~~~~~~~~~~~~\ lineater,\~~~~~~~~~~~~~~~~~~~~~~~~~~

so far this is the only source i have worth contributing, hopefully
more will follow, this is a .h file i wrote (with some help from a
friend at CWRU) that describes the format of the header for atari .o
and .prg files:

```
/*   atst.out.h    .1   24Dec85  */

/*
 * Header prepended to each Atari ST .prg file
 */
struct exec {
     short   a_magic;  /* magic number */
unsigned long a_text;       /* size of text segment */
unsigned long a_data;       /* size of initialized data */
unsigned long a_bss;        /* size of uninitialized data */
unsigned long a_syms;       /* size of symbol table */
unsigned long a_AZero1;/* always zero */
unsigned long a_AZero2;/* always zero */
unsigned short     a_isreloc;    /* is reloc info present */
};

#define   CMAGIC    0x601a        /* contiguous text */

#define   ISRELOCINFO    0    /* relocation information is present */
                  /*  any other value - no reloc info  */

/*
 * Macros which take exec structures as arguments and tell whether
 * the file has a reasonable magic number or offsets to text|symbols|strings.
 */
#define   N_BADMAG(x) \
    (((x).a_magic)!=CMAGIC)
#define   N_TXTOFF(x) \
     ((x).a_magic==ZMAGIC ? 1024 : sizeof (struct exec))
#define N_SYMOFF(x) \
     (N_TXTOFF(x) + (x).a_text+(x).a_data)
#define   N_STROFF(x) \
```
~~~~~~~~~~~~~~~~~~~~~~~~~~

```
     (N_SYMOFF(x) + (x).a_syms)

/*
 * Format of a relocation datum.
 */
struct relocation_info {
      int r_address;    /* offset from beg of Text Segment of */
                  /* 1st longword needing relocation    */
unsigned char r_offset; /* reloc offset byte */
};

/*
 * Format of a symbol table entry
 */

struct   nlist {
      char    n_name[9];    /* symbol name */
unsigned short     n_type;       /* type flag, i.e. N_TEXT etc; see below */
unsigned long n_value;  /* value of this symbol (or sdb offset) */
};

/*
 * Simple values for n_type.
 */
#define  N_BSS    0x0100        /* bss */
#define  N_TEXT   0x0200        /* text */
#define  N_DATA   0x0400        /* data */
#define  N_EXT    0x0800        /* external */
#define N_EQREG   0x1000        /* equated register */
#define N_GLOBL   0x2000        /* global */
#define N_EQU 0x4000        /* equated */
#define N_DEF 0x8000        /* defined */
```

---

it has a problem (at least on VAXen) that C likes to add a half word
of filler after the magic number in the start of the header, anyone
have a work around for it?

A $400 computer is a toy.
A $400 computer that costs $800 is an expensive toy.

The point is that instead of making the ST sell for $400 they should keep
the price the same and improve the ST.

I have somewhat more in mind by "improving the ST" than adding $35 worth
of RAMs.

I ran across an article someone got from Compuserve recently on how
the soon-to-be released ROMs should be installed in the 520ST. As I
was installing my 68 ohm resistors (yes, I'm paranoid) I thought I
would see if my machine's ROM wiring matched what was stated in the
Compuserve article by Keith Hope of Batteries Included. It doesn't.
In all fairness to Keith (who I'm sure had a different vintage machine

or something) the article mentions very early that any deviation in wiring in the machine the reader is upgrading from what was in the article would render the article unapplicable. He's right. Let me give some examples:

> There should also be a jumper wire running from pin 3 of resistor
> pack RP2 to a solder pad in the notch of socket U3. If not, your
> on your machine is different than mine and you are on your own!

No jumper on my machine.

> Mark and remove the two EPROMS from sockets U4 and U7. Store them
> in anti-static material.

I've got two mask programmed ROMS in U4 and U7.

> Install the 4 bypass capacitors in locations C1, C2, C4, C7. This
> may require that the joles be desoldered first.

C1, C2, C4, C7 are already on my board.

> Remove the jumper from RP2 and U3.

No such jumper on mine.

> Remove the solder bridges from the underside of the EPROM sockets
> joining pins 27 & 28. This is important! Check for solder splatter
> and make sure that the pins are still properly soldered to their
> own pads.

No solder bridges on any pins of any of the sockets on my beast.
Does this sound redundant?

> Carefully jumper pin 3 of RP2 to pin 27 on all 6 EPROM sockets in
> a daisy chain fashion. This finishes correcting the alterations
> Atari makes to the board so they can use a pair of 2764 EPROMS
> instead of the 27256's the board was made for.

Ah ha! This is the root of the confusion! My board has ROMs, his had 2764's. This probably explains everything! The only thing I forgot to do was to check continuity between RP2 pin 3 and pin 27 of the sockets. I'll bet that connection is already there, too.
My guess is that my system has ROMS with 27256-like organization (same as the final ROMS) and has all the right stuff already in it.

The article continues with parts locations, etc. but the point I wanted to make was that perhaps on machines such as mine the ROM installation may be as simple as yanking out the two old ROMs and sticking in six new ones (in sockets no less). Wow!

If you are reading this and really know what the installation process is for MY machine, please let us all know.

I have not seen any 520ST+ (1040ST without disk drive) here with TOS in
ROM. The reason for this is, that the German language is much more
redundant than the English language. So the German TOS is always a
little bit bigger than the US version. Why have those cracks at ATARI
not put the desktop resources into a file, in order to load this
from disk when booting?

Why does this surprise you? I have programs written in C, Fortran,
As, Lisp, and other languages which all produce binaries which
work happily on the same computer, even though they are totally
incompatible with each others compilers.

It is always better to make source available as well as executables,
(perhaps offering the sources by mail, to reduce net costs), but
executables still offer the widest distribution of the program's
functionality.

Given an RF modulator output, it isn't too hard to add a composite output
(which is basically the signal fed to the RF modulator input).
Making your own RGB signal is probably also possible, but requires much more
thought/design effort. If anybody needs engineering assistance on this, I can
probably talk a friend of mine (who is a video expert) into helping out.

One thing that has been missing from these discussions is the great potential
the "toy" St now has for education. High schools can afford a good many STs
and can therefore make them available to more students. I wish that there
had been a $300 68000 machine when I was in high school...

Summary:

Some of us are thinking about a cross development system (running on
Vax BSD4.2) for C programming targeted for the 520ST. On and off, we
have heard about the SUMacC (sp??), developed at Stanford, for the
Macintosh. If this is in the public domain, we would like to begin
our work with it.

If you know more about SUMacC and how we may get it, please send me
email.

>I still can't decide between an ST and an Amiga...

The ST has no speech synthesis in hardware, although I've heard that

several people are working on some software based stuff. Also, I don't imagine it would be too hard to add a speech synthesiser to the RS-232 port.

By "sound digitization" I assume you mean a built in synthesiser of some kind. Well, there is the General Instruments sound chip (I forget the actual chip number), and it does provide some very limited control over sound generation. If you really need the control and flexibility that digital synthesisers offer, than I would suggest you use the ST as a MIDI controller for an external synthesiser such as the Casio CZ-101 (very reasonably priced entry level MIDI synth.). Several companies are presently developing MIDI software for the ST and I imagine it won't be too long before the ST really takes off with musicians.

The ST does offer the ability to change screen colors "on the fly" by changing the color palette hardware registers. Tom Hudson presented an excellent article on this subject in a recent Analog magazine (either December or January, I can't remember which). For another example of the ST's ability to display more than the 16 advertised colors, look for the public-domain "paint" program called "NEO".

Contrary to popular (unpopular :-) opinion, the ST does support a limited amount of multi-tasking. Although I've just begun to find out all of the details, I have been able to figure out that the GEM desktop is in fact a multi-tasking environment in which each of the desk accessories is sharing CPU time, with one particular accessory being the "foreground" task. Sorry I can't inform you any more as to the multi-tasking potential the ST has to offer (for my purposes, I don't need GEM or multi-tasking so I haven't spent a whole lot of time studying in either of these areas).

About the double/single sided disk question you had - I needed two drives before the double sided drives became available, so I bought a second single-sided drive. Sorry, I can't help you with that one.

One last thing; it has been very interesting watching the Amiga v.s. ST debate on the net these last few months. I've tried to stay in the middle of the argument - not leaning one way or the other - but I have found myself (on occasion) taking exception with some of the things the Amiga people said about the ST which were just not true. After reading my last reply to one of these articles, I decided not to participate in the debate any more (it wasn't very neutral). To make a long story short, it may be to your advantage to not listen to any emotional arguments about either machine. Being an ST (and soon to be, Amiga) owner, I have no problem stating that the Amiga certainly has some big advantages in it's favor. However, I also know for a fact that the ST offers more raw computing power per dollar than any other computer on the market. Hopefully, there is a place in the altogether too BLUE computer market for both machines to prosper.

Actually, you should look at the actual overhead on a UNIX system before coming up with that 50% figure. On a loaded VAX I can believe 20-40% average over ten minutes or more, but not 50%. On a single user PC-based UNIX system, such as XENIX or PC/IX, that number might change, but I would normally expect it to be lower, and it is on the systems on which I've been able to measure.. CPU time is a lousy measure, since systems such as MSDOS and CP/M spend 100% of their time in a CPU loop while waiting for keyboard or disk input. Your program doesn't run at all! No one could deny that these systems are widely used and useful.

Who decided that large segments of the industry don't want it? I have the feeling that the reason IBM and Cray are now offering UNIX is not because they love AT&T, but rather that people *do* want it. Sperry offers UNIX from its PC's to its top mainframes... same reason!

SystemV UNIX has the ability to do locking. Records structure is an application concept and has no business in the o/s. To complain about the lack of locking in an older version of the o/s is like bitching about the lack of smog control on the model T Ford. It wasn't there because it wasn't needed at that time. UNIX was not originally a business o/s.

>>
>>   Are you aware that Dennis Ritchie once said that if he had
>>known about Tenex, he never would have invented Unix?

I don't dispute it, but (a) I would like to know the source of the quote (published paper, informal net note, remark at a party, you heard about from a friend, etc), and (b) I'm not sure I believe it. It wouldn't have solved the problem of a multitasking o/s on *cheap* hardware.

Exactly the point I was making about locking. It wasn't a goal, it is now, we
have it now.

Keywords: ATARI 520ST, 50/60 Hz, 110/220V, PPAL/NTSC

 Hi this problem may be of general interest of all PC users but
since I have already decided to buy an ATARI 520ST and since this
news group is VERY informative I would like to adress this question
about system compatability here.
 I would like to buy a system that :
1. I will be able to use it here
2. I will be able to use it in Israel where theu use european

standard.
I thought of two possible configuration :
1. The current standard system with the 70Hz scanned-screen
2. A system with a SONY TV as monitor since these TV systems
have the option of 110/220V, 50/60Hz and NTSC/PAL so
I will be able to use it also as a standard TV in the Holyland.
I will appreciate any comments on :
1. Wil it work or not, why and whynot.
2. Any reference which may clear this problem
3. General problems when transferring PCs from here (the promisedland)
to there (The .....)
Yosi
p.s. What are the system standards used by our European friends ?

Summary:

Your point about posting to a source group is well taken. I would like to see pc, atari, and amiga groups in net.source, for this reason. I would be just as happy with mod.source.<those things>.

I have to disagree about the utility of binaries. I many cases these computers do not come with the compilers, etc, needed to regenerate the binaries from source. In other cases the source *is* proprietary, while the binary isn't. This can involve use of a local or licensed library to perform interfacing, etc. I would rather have something for nothing than nothing at all.

There is little reason to worry about a binary "trojan horse" on these machines, since there are no "outside users" to get at information, and the o/s manages to trash the file system often enough without help.

PS: I think the atari make a GREAT output terminal for color graphics on a UNIX box, but I wouldn't buy a development system to compile source, since that's not my intended use. Binaries are fine, they allow other use for my graphics subsystem.

Why should anyone get upset over the "toy computer" name? Let's be
honest here: both the Amiga and the 520 ST are toy computers, as
are virtually all "home" (as opposed to "office") computers. I
don't mean that they have minimal capabilities, I mean that they
will be used for personal amusement.

Whether that amusement is in playing games or in hacking, I don't think
there's a difference. The computer is being used as a plaything.

Enough guessing as to what the prices will be! The "Scientific American"
issue this month contains a full-page ad for the unbundled ST available
from JS&A. It gives prices for the basic system unit, both monitors, and
the disk drives. The TOTAL cost is about the same as the cost in computer
stores, and a little greater than you can get now by mail order. This is
about what I would expect from JS&A - you can normally do as well as they
offer locally, and rather better if you try other mail-order outlets.
The important fact is that this is the 520ST with the built-in RF converter,
so you can use it with your own television. But the ad does state that you
can use the Atari monitors with this version of the ST, so at least we now
know that the RF converter is in addition to the direct monitor connection
rather than a substitute.

I was seriously considering buying an Epson JX-80 color printer

for my 520ST. I took my ST to my local friendly computer shop
and hooked it into the JX-80, then I used the install printer
routine to install a color printer. When I attempted to
do a screen dump to the printer, the operating system hung up
until another command was given. If we installed the printer as black
and white it worked fine in graphics and text mode (only black
being printed by the printer). Does anybody
know if this is a bug in TOS or if another color printer will
be supported? The JX-80 is a tempting printer and I hear that
price cuts will be coming soon. If anybody else has thoughts
on this or experience with color printers I would appreciate
hearing about it. Also, does anyone know if DEGAS or other
graphics packages will have JX-80 printer drivers?

Presumably the "analog RGB" output is synced at 60 Hz, else very few RGB
monitors would work right on it. Or is there a way to select (there must be)
a 60-Hz output? If so, then it wouldn't be too hard to whip up a composite
video signal from the RGB, or even a 60-Hz monochrome one. On the other hand,
a 60-Hz composite signal must exist at the video modulator input, so it could
also be sneaked off from there. Then at most a low-pass filter would be
needed to feed a 60-Hz monochrome monitor, and in fact the composite signal
could probably be used, as it was designed to be more or less compatible.

Does anybody know whether the whole thing shifts gears to 60 Hz when you plug
into the RF modulator jack? Or can you simultaneously run RF at 60 Hz and
monochrome at 70 Hz? This may be the key to why you can't run both monochrome
and color monitors at the same time -- if in fact you can't.

The materials packaged with my recently-purchased Atari included the following
phone number:

     (800) 538-8543.

I hope it is less overloaded than the ones you mentioned; I haven't tried
calling it.

its been said before but i'll try saying it again and see if anyone
listens. This group is all talk and no substance, all quantity and
no quality ! the amiga group is alive with helpful suggestions,
major source code (MicroEMACS, make, more, etc.), all we seem to be
able to do is yelp about atari's marketing practices, unix and MMU,
unix and flexability (what the blue blazes is that doing in this
group?), and blah and blah and blah. Are we so insecure that we must
constantly re-enforce our decision to buy the ST ? what will make or
break this machine is what WE do with it not what the hardware does.

Please don't prove my point by posting a bunch of trivial (or
otherwise) flames to this group, email them to me and i will
summarize them.

FLAME OFF

Incidentally besides OSS Pascal, TDI is now distributing Modula-2.
Don't know the quality of this Modula-2 implimentation but it would
be interesting to find out.

So far i am aware of the following languages available or planned for
the ST:

  C:

     DRI/Atari Development Kit $300 (available)
     Megamax C $199 (available)
     Philon C   (?) (?)
     Metamaco Lattice C   (?) (available)
     Aztec C   (?) (first quarter 86)

  Pascal:
     OSS Personal Pascal $80 (available)
     Metamoco Pascal   (?) (i believe currently available)

  Modula-2:
     TDI Modula-2 $70 (available)

  Lisp:
     Metamoco Lisp   (?) (unknown release date)

  Prolog:
     OSS Personal Prolog   (?) (March 86)

```
  Forth:
     Dragon Group Forth      (?)  (Available)

  Basic:
     Atari Basic                      ?free (Available)

  Logo:
        Atari Logo                        ?free (Available)

  Assemblers:
        Metamoco Assembler                (?)   (Available)
        DRI Assembler with SW Dev.Kit     (?)   (Available)
------------
I would appreciate if this news group would concentrate on updating these
type of lists as a source of general information.  As someone finds out
about a new language, post the news by adding it to the above list.
Perhaps adding the manufacturer's address is the next step.

Let's try to make the atari/amiga diatribes a thing of the past.
I think that subject has been talked to death.

"Use the source, Luke..."

In article <505941353.strauss@GANDALF.CS.CMU.EDU>, Daryll Strauss writes:
> The problem with posting sources is that many sources are compiler
> specific, and many people don't want to muck with the code to get it to
> compile. And a lot of people don't even have the compilers.

I can't sympathize with somebody who has a Usenet connection but is
too cheap to buy a C compiler for their machine.
```

If you receive a source and don't have a compiler, you can always find
a friend or a user's group where you can compile it.

I understand that a lot of cheap hacks are "compiler specific" but
it seems like if you're going to post something to a thousand sites
(at their expense and with your name and reputation on it), it would
be worth sending it to a few friends first to make sure you have made
it portable. Many people in the Unix world take great care to do this
with their postings, and it shows. It *is* possible to write
compiler independent and environment independent programs -- look at
netnews as an example. The code quality is pretty bad, but it *does*
compile and run just about everywhere.

Especially with the Atari and Amiga, there is a "standard" C compiler
and libraries, that you can buy from the manufacturer. Newer compilers
will have to follow those standards to be successful. This was a big
problem on the Mac but let's leave the Mac's problems behind us instead
of dragging them into the Atari world.

Hey! I've noticed that everybody's posting sources for the Amiga now.
It's just the Atari folks who are holding out. Maybe you-all are
afraid your code will end up running on (shudder) Amigas?

     This is somewhat heterogenous group of comments/questions on the ST.
1: What is exactly the connection between the ST OS and CP/M-68k? A lot of
   comments on the net seem to be based on the appearance of the references
   to CP/M-68k in the dev's kit, which has borrowed documentation from what
   seems to be the previous implementation of GEM. But the documentation also
   has references to other OSs. Someone once said that the OS is really based
   on MS-DOS. In one magazine is a comment that the command line looks like

a typical CP/M-68k command line. But this doesn't seem like really strong evidence to me. Does anyone out there really KNOW what the history and nature of the present system are, and therefore whether or not the OS is any closer to CP/M68k than any other system? I suppose I should just phone directly to the creaters on this one.

2: On the class implications of the Amiga/ST marketing difference, may I say that there seems to be a lot of snobbery in the computer market that is becoming increasingly well delineated by the Amiga/ST war. There seem to be computers for people with suits, and computers for the common people. The former are associated with pot-plants, high prices, and a certain sophistication of presentation in software and documentation, whereas the latter are associated with cut-throat market competition, kids and workers and fanatical enthusiasts, and rushed documentation (not to mention mail order companies, K-mart and toy shops). All of this imagery is to a great extent reminiscent of the 1st, 2nd and 3rd class train travel of british colonial days. (Not to mention plane travel of nowadays.) The rich were willing to pay extra for the right to not have to company with the hoi-polloi, which is to say, the riff-raff. The high price was designed not to cover extra costs, but rather to dissuade the poor. Rumour once had it that Amigas could have been $400 less except that then the business computer users would not take it seriously. The recent fluster over the change to ST marketing reinforces the belief that many amiga buyers have bought the high price machine in order to have the best on the block, to to be one ahead of the others, which is to say, to maintain their distance from the riff-raff (variously described as users of toys etc.). Please, observant persons on the net, read the Amiga/ST factional rivalries and ask yourself whether you think it is worthy of a modern egalitarian civilisation to foster class rivalry?

3: Could anyone inform me please as to why the net.micro.amiga can have megabytes of source code whereas this seems to be against the rules for net.micro.atari? If I write something of general interest, would I be doing something wrong by posting it?

4: An aspect of ST use that is dawning on me is that the true cost of the mon system is $1400. Reason: the ST is not much use without the dev kit. And the dev kit is not much use without a second drive. Total cost: $800 + $321 + $300 = $1400 (to 2 sig.figs.).

5: A magazine once said that Atari should get a lot of business from those who wanted an Amiga but will settle for an ST (by analogy with the Apple II nad C-64). An impression I have is that the Amiga is for those who wanted (perhaps not consciously) a microvax. One of the big attractions of the Amiga is its OS which has some multitasking in it. But a lot of people don't seem to have noticed that the ST OS has what they call "limited multitasking". In fact, the ST can handle some 7 or so processes of a user nature, in addition to monitoring the mouse when it goes off the upmost window. Programmers are specifically asked to write programs that give themselves up now and then to AES so that they can be repalced by another task. Has anyone had any thoughts on how to modify this "non-preemptive" scheduling to make it preemptive? This would make the ST some what more useful. Incidentally, Robert Frick once said in answer to my question about the lack of an MMU, something like: Why have an MMU, it just slows down the processor?
The only real uses I think of for multitasking in a "home environment" (ie at home) are for bacground processes to print jobs and down/upload

files. Perhaps also for solving large mathematical problems. But really the main reason for the invention of multitasking was, I believe, for the sake of increasing efficiency for a multiuser system. What are all the Amiga users doing with their multitasking capability? Is it just to give them a sense of power, or is there something I've overlooked.
The multitasking seems to be giving them some real problems. Like copy-protection. An application that does not want to be copied has to prevent simultaneous processes from running. Hence it seems that copy-protection implies no multitasking. This makes it difficult for the high-class software establishments to justify an investment in multi-taskable programs.
On this point: I've seen a copy-protected ST game program which achieves its purpose by using the boot sector of the disk. This is going to be really easy to get around. The dev kit tells you so much about how the ST works that I belive copy-protection is going to be difficult to achieve on the ST too.

6: I've lost count. Is this really number 6? Anyway, on the subject of monitor screens, I've just had another look at the Amiga with a view to its high-res screen capability. What a joke! Its worse than any description I've ever read. If anyone is going to call a machine a toy, then the amiga is the one to criticise. I got the mono ST screen because serious work requires an informative interface, for which I really wanted a Mac. But I was willing to settle for an ST. (I've since discovered that the ST is better hardware and OS wise.) But really the fact that Commodore have not provided a decent monitor screen shows where their interest lies. Having now seen the high quality of the development tools provided for the ST, I realise that ST is, for my purposes, better than the Amiga, even at the same price. And everything that the ST lacks should be easy to add on. Eg synthesisers, voice etc., which I'd rather choose personally than have built in.

7: On the meta-subject of how net.micro.atari discussion should be conducted, may I suggest that non-productive position-taking, mud-slinging and general defense of one's purchase be accompanied always by at least one serious comment or question about the ST that is relevant to the purpose of writing programs and such for it? If everyone had to do something constructive in each of their contributions, there would be a lot less discussion on net.micro.atari.

8: My apologies for the length of this message. There were a few things I just felt I had to say and ask. So long.......Alan Kennington.

I routinely use Atari Kermit with a UNIX-like system (a BBN C/70) via
a TAC (version 113).

First - set the intercept character to be something Kermint doesn't use. I
use (ctl-F). Do this with the sequence "@i 6." This sets the TAC commmand
interpreter recall character to something you can still type, and therefore
still get back to it. If you say "intercept none (@i n) you can't get back.

Next - enable flow control with two commands (@ f i s and then @f o s) which
start input and output flow control. These two sequences enable XON/XOFF
flow control, which allows the TAC to temporarily shut down the Atari to
TAC direction, which is usually the bottleneck. The usual problem solved by
flow control is that the TAC terminal input buffer is usually set to 64
characters.
Since the default KERMIT buffer is about 90 characters, it is easy to overrun
the TAC. A second strategy here is to set the KERMIT block size to something
less than the TAC input buffer size (less than 64). I have heard rumors of
some UNIX KERMIT servers which negotiate you back up above 64 characters,
unbeknownst to the user, so try the flow control dodge if small blocks
don't work. There is also a penalty to small blocks - lower throughput.

Unless youknow you are doing binary data transfer, which I haven't tried
with my KERMIT (I don't think it does it), don't fool with the TAC commands
@b i s and @b o s. I don't think they do anything helpful for you.

I use the standalone version of Atari 800 KERMIT written in ACTION!
by Jack Palevich. It seems flawless. It also has a nice debug mode in
which it prints out everything that's going on. The sources floated
by on info-atari many moons ago. It seems to need the cartridge, which
is fine with me.

I use the above aggregation on a DOS-XL system, with a an R-Verter RS-232
port instead of an 850 box.

AXM

P.S.

Note that in the above, once you have re-defined the intercept character,
you must type the new intercept character where you previously would have
used "@."

> Bug in RAM TOS.

If you double click on the disk ICON, and then RAPIDLY click again,
the mouse clickard will start auto-repeating. After a while, magically,
the desktop wakes up and reopens the drive. It is irritating but less
painfull than reboot.

And now for something totally different.

Anticipating a hard drive, I have started writing backup utilities. Step
one was a mandatory clock verification routine for the boot sequence.
It works fine, but the !@#$%^&* desktop gets loaded after the
auto directory contents get run, and the brain damaged piece of
code sets the clock to May something-or-other 1985.

I know that one of the applications allows me to reset the clock after the
desktop starts running. That is fine, but I've thrown all the desktop
applications out to get more RAM. Also, if I don't have to set the clock,
I will forget to do so, and files get timestomped with the wrong date.

So the question is: does anyone with the ROM TOS know if this feature
is retained? or, has anyone got some hack to fix this?

Come to think of it, I am probably going to buy the K-Mart Special, since
it obviously has been modified to scan at 60 Hz. It will be MUCH easier to
add a Composite or RGB output to this version than the 70-Hz version! The
composite monitor output may even be provided, a la 800XL. If anybody knows
or finds out what other options are included e.g. RS-232 port, etc., please
post this info to the net!

For the Centronics parallel port, there is another interface available which
sells for $89.95 at The Bit Bucket, West Newton, MA. I dunno the name of the

manufacturer but can find out if necessary. Phone at The Bit Bucket is
(617) 964-3080 and incidentally they stock (yes stock) both the Amiga and
the Atari 520ST (as well as 800XL and 130XE and a whole PILE of software).

Does anyone know if a monochrome ST can be used with a Commodore 1702
RGB monitor (after unplugging the monochrome monitor of course)?

Another way of stating this question: Is the color output of the ST so
unusual that a non-Atari color monitor cannot be used?

Thanks.

"Until there is a net.micro.atari.source I will post ALL sources for the 520ST to net.micro.atari and net.sources"

No - don't do it! *Pleeeeze* don't do it. I read my mail on a Dandelion on a 10 meg Ethernet and I find that one 68K file (that I can't even use) slows down mail retrieval noticably. What about all those poor people trying to get by with 1200 or (gak) 300 baud modems?

On another subject, I upgraded my 400 to 48K with no problem. My Indus drive arrived last week and it is quite an impressive piece of hardware. My only (minor) complaint is that despite the metal case it seems to leak a lot of RF. It took a bit of cable twiddling and box moving before finding an arrangement that produced a herringbone-free screen.

- Michel

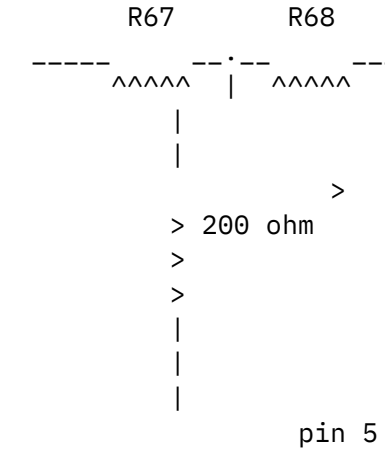
Has anyone tried the solution for the lack of chroma in the 800XL that was published in the February ANTIC i/o board column? Essentially it says that the chroma output is at the emitter of Q5. You need to connect

a 200 ohm resistor from the junction of R67 and R68 to pin 5 on the monitor connection. Credit for this goes to the Chicagoland Atari Users Group.



Note: resistors R67 and R68 actually are next to each other and not back to back as this diagram would indicate. I have intalled this on my 800XL and the picture I get on my C*******e 1702 monitor is identical to that of my 130XE. (I would suggest to install this on the bottom side of the board. It is easier to get outside of the shield that way and also it is easier to solder.)

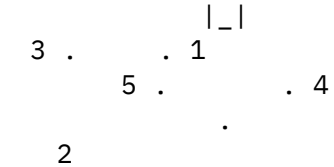
Question: the diagram for the 130XE shows --
        pin 1 composite luminance
        pin 2 ground
        pin 3 audio output
        pin 4 composite video
        pin 5 composite chroma

-- the 800XL still has one pin not used (I think pin 4), what does this
   mean? Should this remaining pin be connected? If so, to what?

Then on the 1200XL, I find that pin 5 is not connected to anything, but pin 4 is. Is pin 4 composite video on the 1200XL and if so, should I connect pin 5 to pin 4 or to something else (on the 1200XL)?

I find it hard to imagine that the 130XE requires five pins connected and that the 800XL and 1200XL only require four pins connected. And not the same four to boot!!!

By the way the pin configuration (per the 130XE manual, as looking at the connector on the computer is:



[Only Atari would not number these pins consecutively!]

To Whom,
I have been trying to get off of this DL for some time now and have
requested info-atari-requests@su-score.arpa to do so...whereupon, I was
informed that I wasn't on their list, I subsequently checked to see if
I was getting a redistributed copy from SRI, which I'm not. So, this is
a plea to you to please check your info-atari DL and remove me. I'm still
getting mail and I noticed much of it was forwarded from you to SU.

Thank you for your help, Glenn

Has anyone out there used the Mail Merge portion of AtariWriter Plus TM?

I first tried to load my old Atari Maillist files to Mail Merge. That did
not work as the format was not fully compatible, even after setting up
Mail Merge to match the Maillist format. Does anyone know how to convert
Maillist files to Mail Merge?

Therefore, I created new Mail Merge files with format that I liked and
edited in one file at a time all of my old Maillist files. However,
when it came to print them out, I cannot find anyway to format the
output for the printer. Creating a subset seems to be a way of sorting
out a portion of the files by whatever catagory. What I want to do
is to place the first name field, then the second name field then the last
name field on the first line. Followed by the street address next line.
Third line to consist of city, state and zip. Not too complicated but
so far I have not figured out how to do it. Any ideas?

Finally, is there anyway to increase the field length past the 20 characters
allowed by Mail Merge? 20 characters is ok for most fields, but for street
addresses, it is sometimes too short. Any ideas on this?

Thanks in advance,
--Bill--

~~~~~~~~~~~~~~~~~~~~~~~~~\ lineater, \~~~~~~~~~~~~~~~~~~~~~~~~~

MERDE!!! are you saying that a compiler may not compile the source
but the computer can run the binary ? i find that hard to believe !
I agree tho with your solution, posting both is the best of both
worlds, if size is a problem then uuencode it, there are decode pgms
for both unix and the ST.

One way to get GEM info is to buy O.S.S's Pascal compiler (under $100). You will not get the standard GEM interface but O.S.S. has made most of GEM accessable through special Pascal procedures and functions (standard gem calls can be linked into you program as well, but there is no doc for this). Using the special routines makes it relatively easy to set up windows, drop down menus, and dialog boxes. Ease of use and length of compile time is also much better than DRI C.

John

In the Amiga case, you are getting $40 million dollars worth of TV advertising
plus the opportunity to pay off Commodore's huge debt for the mistakes AFTER
Tramiel left.

>
> At this point, I think we ought to stop the silly Amiga vs. ST debate

Agreed. It is very silly. Given two comparable computers, one $1500 and the
other $300, the debate is ridiculous.

P.S.: I really do like the Amiga computer; I just hate the price. (And I love
all that memory on the new 1040 ST, and what about homebrew upgrades to 2 MEG!!)

*** REPLACE THIS LINE WITH YOUR MESSAGE ***

The C source for megaroids is not in the public domain only the
binary file is. If you want a copy of the C source call 214-987-4931
and for a small fee they will send it to you. Also this program will
run only on a Atari 520st color system. Therefore only owners of
520st color system would use it, that is why I posted it to
net.micro.atari and not to net.sources.

If phone bills are a problem for some sites then we should create

a net.sources.atari newsgroup. I feel net.sources is for
portable UNIX or C programs and not the place to put hardware
specific programs. If you don't think a net.micro.atari.source
news group is appropriate, then maybe we should remove net.sources.mac
from the net!

Thiis article is posted in response to inquiries I have received
with regards to ST COMM, a program I wrote with the HABA HIPPO C
compiler. As posted, and using the HABA HIPPO C compiler, the program
comppiles and runs withoout error. If one attempts to compile it using
the DRI C compiler provided with the development package, errors will
result. I was unaware of this until Alan Kenington wrote me. His
analysis seems to make sense:

> HABA HIPPO C defines an 'int' as a 32 bit quantity. DRI C
> defines an 'int' as a 16 bit quantity. Alan says that the
> errors occur with the 'switch (c)' statement; and they are due
> to the different 'int' representations of the compilers.

I hope this helps anyone encountering these errors. It has been a while
since I posted the source, and I am not thhat familiar with it anymore.
Maybe Alan will read this and repost his analysis for all to digest.

> drive is put in the dealers package, current owners should be able to trade up
> to the DSDD drive or in some way be compensated.

A nice idea, but don't hold your breath! As I write I can see the 520ST system
that I bought (for $1400 - I've got both monitors, and a second (DSDD) disk
drive).
I would really like to be able to upgrade this to a 1-meg system *without* blowing
my Atari warranty away. I can (just) see Atari offering me this at a reasonable
price (as I have also purchased their development package), but I do not believe
they will do anything about the disk drive.

I have not really got into playing with the ST yet, as I'm still waiting for my
C compiler and all the documentation, but I do have a couple of first impressions
to share with the world.

- The first thing you are told to do is make a backup copy of your system
  disk. SO WHY DON'T THEY GIVE YOU A BLANK DISK TO DO IT ON ? (The same
  goes for the language disk, if you *really* want to use Atari-LOGO).

- The actual internals of the machine are plenty powerful enough to make
  this thing a real computer, not a 'toy'. (This message is being written
  on an Apollo workstation. The main CPU is . . . . . a Motorola 68000).
  WHY DO I HAVE TO FIND ROOM FOR ALL THOSE STUPID EXTERNAL POWER SUPPLIES ?
  I have to find FIVE places to plug everything in, and somewhere to put
  the power supplies as well as all the system components. Package the

system like a video game, and people will think it is a video game.
(After all, the converse is true - a well-known company packaged a 8086
like a computer system, and thousands of people believed it really was
a computer system :-)

I am leanly towards getting a 520ST, but I have a few questions.

1. I have read that real soon now we will see the 1024ST's, has anyone
seen one of these yet??

2. Anyone who has priced 520ST's in the L.A. area want to let me in on the
best deals they have located. If anyone knows of a good mail-order house
with a good price let me know. Most of them list 520ST $CALL.

3. I would love to know if anyone has used the Modula-2 available from
England. I tried the Mod-2 for the Mac, tossed the disk and sold the
Mac.

4. Does the developers kit give ALL the stuff one would need for getting
into the nuts and bolts of the 520ST both hardware and software wise? I
noticed one posting where someone was bragging that the 520ST had better docs
(hardware schematics ect..) then the Amiga, but soon after that I find a
sequence of messages asking about how the DMA port worked. Just how good
are the manuals in the developers kit??

5. There simply has to be a way of getting memory. What does one do after
he has piggybacked 1 meg? Has someone come up with a two meg scheme yet?
Would one be able to piggyback a 1024ST and get a two meg machine? Byte, in
the January ish, just had a PREVIEW of the 520ST, what does one have to do to
find info on the 1024ST?

6. What I want is a machine with good, sharp text (sorry Amiga) that has the info and tools available to get inside the machine. Most importantly I want to be able to compile programs quickly. Does your 520ST give you these abilities?

7. I've been hearing about the system ROMs will be here real soon. Has anyone out there actually run down to your dealer and picked up a set? Has anyone seen the harddisk yet? At what price?

Just mail this stuff directly to me please. Thanks for the time.

P.S. I would love to see more "hey I just got this and it sucks" or "this is great buy for the money" info, or even something more in depth then whether Unix can be ported or the Amiga sucks. For example lets find out what is the best C out there for the ST ect... I hate to say it but the amiga board seems to be slightly more informative.

Thanx,

Ray

Has anyone used a Commodore 1702 Color Monitor as a monitor for a VCR? What does it take to hook it up? Just to RCA to RCA cables? Or what? Am interested in renting a VCR and would like to be able to use the monitor for the picture. I realize that this does not have too much

to do with computers, but did not know what other groups there were
to address.

Thanks,
--Bill--

Brenda,

I had the same type of problem when I got an account on Delphi. There is
a solution, Russ Wetmore (Homepak's author) wrote a Hometerm customizer.
You can get it off of DL2 in SIG Atari - 8 bit (I'm pretty sure) on
Compuserve. This program lets you get rid of the unneeded linefeed and
tweak several other variables. There's good documentation for it too.

If you have trouble finding the program, Russ spends a lot of time on
compuserve and is always helpfull, or ask any of the Sysops.

Good Luck!

One of the many affects of this kind of market repositioning is that some
third party developers (mostly in harware, In my opinion) are either going to
halt or pick up developments because of the price change. On the plus side,
I think that the price drop will stimulate development and use of the ST.
On the negative side, companies that might have considered the ST for
professional use (do they exist?) might reconsider.

So called "professional" products which could cost $1K-$50K each seem
somewhat rediculous when paired with a $800 computer. A $400 dollar
computer you say? Forget it. Why would a company soil its professional
image associating with the rabble :-).

This is one of the nice thigs about using DOS-XL (2.3 or later) with OSS's
Supercartridges (like the ACTION! and MAC/65 carts; these are the cartridges
with bank selects etc.). The DOS actually comes in two forms, and you're
supposed to install one depending on the setup; one for supercarts without
XL machines (ie. the 400/800s) and the other for XL machines, on which
the DOS moves part of itself into the RAM hidden behind the OS, freeing up
some space. So, using a supercart with DOS-XL on an XL machine one could
probably be able to hide the cartridge under 4K only.

The problem with MEGAROIDS is that it is a demo from MEGAMAX for their
C compiler. My version says that the source of the program is
available as a hardcopy from MEGAMAX for $25 (don't know the address).
Therefore nobody may post the source.

bit-blitting: BITBLT = Bit Block Transfer. It means being able to move
data from one memory area to another without the requirment that the
transfer begin and/or end on a word or byte boundary. e.g., "Move N
bits from here to there." Useful for putting a bit map up on a display.

>(and VENIX, Xenix, ...) on IBM PCs doesn't really count as secure.
>(Ergo it's not UNIX.) Processes can mangle each other at will.
            ^^^ ^^^^ Nonsense! It works find as UNIX. It is true
that it is not hacker protected, but most single computer UNIX's
have only one user anyway. To me UNIX is a portable environment
offering a wide selection of nifty tools. That's just what I have
here on my VENIX.
>
>In short, it's not really UNIX there, and it pretty much DOES have an
>MMU. Better than nothing, but I wouldn't buy it. UNIX needs at LEAST
>memory mapping. This can be real cheap! but the 520ST doesn't have it.
^^^^^^^^^^^^^^^ You just haven't shown this. The extreme purist view that
PC UNIX's aren't really UNIX doesn't wash. On the other hand, there is
no denying the value of memory mapping

Yes - really. My old IBM BBS was chock full of binary only programs (with
no source available). Some were Freeware and some were just plain public
domain. So is the ST BBS I currently log onto. Megaroids is being freely
distributed by most ST BBS's. The source is available for $25 from Megamax.

********This isn't really necessary********

In reply to my earlier posting where I commented on what Atari might do for

those that had already purchased the 520ST, John Francis writes:

>A nice idea, but don't hold your breath! As I write I can see the 520ST system
>that I bought (for $1400 - I've got both monitors, and a second (DSDD) disk
>drive). I would really like to be able to upgrade this to a 1-meg system
>*without* blowing my Atari warranty away. I can (just) see Atari offering me
>this at a reasonable price (as I have also purchased their development
>package), but I do not believe they will do anything about the disk drive.

From additional items I have read on the net, it doesn't seem like Atari is lowering the price of the 520ST. Instead, Atari is apparently unbundling the system, but, if you buy all the pieces, the cost remains the same. They do seem to be adding an RF modulator (does anyone know if this capability will be made available to the earlier STs?). If this is the case, rather than a price cut, then some of my previous thoughts are not applicable. In St. Louis there has been some effort to keep earlier ST buyers happy and to promote additional sales of the 520ST package while awaiting delivery of the 1040ST.

Our Atari dealership (Instant Replay) is offering to install the ROM chip for free and perform a 1 meg upgrade for $20 plus parts, if you bought (or buy) the machine from them. They are also offering some discounts that I am not familiar with. The Atari warranty is only for 90 days, I think, but, if the dealership does the upgrade, I would think that they at least would not consider the warranty invalid.

I appreciate this discussion being returned to rationality. Let's keep it that way.

I fail to see the relationship between adding TOS ROMS (which don't
connect to CAS and RAS) and the destruction of DRAMS because of
undershoot on CAS and RAS. I think the problem probably exists when
only the extra DRAM is added.

If indeed the DRAM is being wiped out by undershoot, the resistors
are a very good solution. I just don't think this has anything to
do with the ROMs being installed also (unless there is some bizzare
interaction between the additional load on the address lines and
CAS and RAS in the controller chip or DRAM). If anyone at Atari is
reading this and knows what is really happening here, I'd love to
hear from you.

Rule #1: Use lots of antistatic protection when doing these mods!

[]

Rumors about Rom Tos functionality are starting to float across
the compuserve atari sigs. Specifically:

1) Dialog boxes crash on '_' characters

2) They didn't fix the notorious 3 compile puts the
desktop to sleep problem. (What? run some batch
programs like the compiler/linker a few times, say 3 or 4
cycles of edit - compile - link - run. Eventually
the desktop forgets about all of your open directory
windows.)

Any other bad news out there?

Also, many of us put out $300.00 bucks for the developers package, and
received several items that were distinctly broken, and a few things that
were missing. Namely: the command and batch programs have bugs, the
RSC takes a hike frequently, the archiver, icon editor, and various
pieces of documentation are missing, the symbolic interactive debugger
doesn't function at all like the documentation, and the C compiler has
a few irregularities. While I was pleased to receive the Emacs editor
and the new docs for bios, that was months ago, since then a distinct
lack of upgrades have been pouring out of Atari. What gives?

And finally, before I put out $600 for the hard drive, Anyone got one in
use who would like to report on it?

Oh, finally, I don't care where Atari sells ST's, but they sure as hell
should provide a supported and reasonably priced upgrade from 512K to
1024K. I can't believe the drivel about how selling an ST for $500
bucks makes it less of a machine than if you sold it for $1500 bucks.

I think it is time that people redirected their energies to writing
some useful programs instead of boring us all with this interminable
ST versus Amiga debate. Then we would all be better off. The public
will decide with their checkbooks and credit cards and until then
contributing good programs to the machine of your choice would be
far more valuable to your cause.

From Electronic Engineering Times, Jan. 6, 1986:

Atari Preps 32-Bit Unix Workstations
Mulls 68K, WE32100

Atari Corp. is ready to light the fuse on a series of high-performance, low-cost computer workstations.

The multitasking computer workstations may sell for about $1,000. They will have screen resolution in the megapixel range and may use either or both the Motorola 68000 family or AT&T's WE32100 chip set.

Prototypes of the new workstation systems are said to be working now. Production could commence before the second quarter.

Atari had a less-than-nine-month design cycle for its 68000-based ST system. It is already well-recognized as a serious contender in producing 68000-based desktop computers for between $500 and $1,000.
[Serious contender? Who else is contending? -- DRS]

The $800 512k ST system is gaining momentum as it pursues Apple's Macintosh, and gradually outpaces Commodore's Amiga system in installed units. While company chairman Jack Tramiel boasted last January that he would sell several million STs in 1985, analysts believe Atari will chalk up eight-month sales figures ranging from 125,000 to 200,000 STs.

The AT&T Connection

The majority of these STs are in Europe. The STs went on sale there two months ahead of the United States, where FCC radiation regulations were being met.

Last spring, Atari's engineers were keen on National Semiconductor's 32000 family of micros. That enthusiasm waned when designers found that compiler

and system software for the 32000 family gave the prototypes little more clout than the 68000-based 520ST.

The next system candidates sported a 68000 air. Atari has built 68010- and 68020-based systems that are accommodating to existing ST software while offering the potential for true multitasking capabilities in the future.

But Atari designers also are very taken with workstations designed around AT&T Technologies' WE32100 processor. Prototype workstations with AT&T megabit-RAM chips are being polished as entry-level Unix workstations.

Coincidentally, AT&T has been scouting for both a design and a manufacturer capable of delivering a low-cost system to better spread the gospel of its Unix System V. The Atari workstation design could neatly fill the bill.

Last summer, AT&T managers described as "unfounded" reports that they were courting Apple, AT&T [sic] and Commodore for a low-end personal computer. AT&T admits having had talks with each of the 68000-desktop micro makers. But the topic at that time was not workstations. The talks revolved around the personal computer offerings of each.

I would like to know what kind of protocol the DMA port on the atari 520st uses. Since it is the only high speed port on the machine, it would be nice if it was a general purpose port and not completely tied to hard-disk type devices. Could someone with the developer's kit help me out here?

Thanks in advance,

After seeing all the flames about binaries, I thought I'd ask first. I just posted the C sources to a very good public domain editor I wrote to net.sources. I know most of you don't have the C development system, and I'd be willing to post the uuencoded version of the compiled editor if there is enough positive response. I'll also make copies for anyone who sends a disk and a return envelope. Please check net.sources 1 of 7 and 7 of 7 for the documentation.

I have been trying to get COMPUTE!s MLX Machine Language Editor to work on my
800XL to type in SpeedScript 3.0 from a published binary listing. (Please
hold back your comments on the sanity of doing this when machine readable
versions are available...) I find that MLX itself works fine except that when
I save and reload the program, the data appears shifted, as though one byte
got lost somewhere and everything has been moved forward in the memory image.
The version of MLX I am using is in COMPUTE!s book on SpeedScript 3.0 for the
Atari.

I seem to recall that there was a comment about such a problem on the net a
few weeks ago regarding sector write/read operations. Does anybody out there
know about this? Is there an "approved" fix? Am I causing trouble for myself
by using an older DOS (2.0 or so)? Will the problem magically go away if I
use the 3.0 DOS that came with the disk drive?

Any help will be greatly appreciated.

>(5) build an inferior machine and charge less
>
     So, what do you think is the classification of ST ???
     If #5, in comparison to what ??? There is something
     called price/performance ratio, and ST is well placed
     with that respect.
>
>This is fine for throwaway computers (a.k.a. toy computers), but
>not for serious computers. A software developer writing a

>serious application is going to want the machine to be on the
>market for some time so his software product would be saleable.

Are you saying that if there is 5,000,000 ST's out there,
than a developer will ignore it simply because it somehow
appears to be a throwaway computer because of its cost ??
How about the market forces exerted by a product like ST ??
Or did atari make a mistake by not pricing their hardware
in some inflated fashion ?? And just what is a throwaway
computer ?? C64 ?? Apple][?? Perhaps our stance from
VAXinated ivory towers does not quite mesh with what
that 13-year-old thinks of "throwaway" computers. I have
a feeling that how the ordinary folk think about a computer
is much more important than how this entire net thinks about
a computer.

I would suggest using the LOGO disk to back up the system disk. :-)

Hurray!!!

We are finally getting some source code for the ST on this dl (just like they have on the Amiga dl). Keep up the good work. As soon as I have something to contribute I will return the favor by posting it.

I have been trying to get some information from ATARI regarding some warranty service that they did for me (I am still waiting to get the &(*)(*&@#$ computer and monitor back via UPS.

I tried in vain for two days to get through over the telephone using these two numbers:

1 - (408) 745-2000
          745-4851

Both numbers were constantly busy, and after calling about 20 times at 15 minute intervals I quit in disgust and mailed them a letter. If I am ever have to call them again (God Forbid!) could any of you suggest some other numbers to call that one would have a nonzero probability of getting through on?

Keywords: atari 520ST upgrade onemeg

Does anyone know if Atari will be providing an upgrade path for the current 520ST owners to an "official" 1040ST? I'm not sure I could do the piggy backing myself.

Alternatively, does anyone recommend a shop which does the upgrade to 1 meg? The best I've seen wants $200 for the $50 of parts. Is this

reasonable? Anyone interested in upgrading mine for less?

A while back there was some discussion about commercial alternatives
to the 1 Meg piggy back upgrade. There were a couple of boards that were
mentioned as being in beta test or going to be available "REAL SOON
NOW". Can anybody point me to some of these boards ? Someone mentioned
that one board required no soldering. Any info would be appreciated.

Note that the toy store version must have been modified for 60-Hz frame rate
to ensure satisfactory operation with NTSC televisions.

This means that it probably will also come with a monitor jack that will work
with standard monitors, whereas the Real Computer Store model will only drive
an Atari 70-Hz monitor!!!!

(I have the funny feeling I already said this; if so, my apologies to the net)

I have a few questions about the 520 ST I'm curious about:

    Speech synthesis: is there any?
    Sound digitization- ditto?

    Is it true that, by fiddling with interrupts, one is able to
get more colors on the screen than normally?

    Multitasking- is there any?
    Are double-sided disks and single-sided disks compatible/incompatible
with each other and with their respective drives in any way(s)?

Any meaningful responses appreciated-
I still can't decide between an ST and an Amiga...

While I am considering the purchase of an Atari 520 ST, I wonder if anyone has any knowledge or experience about connecting the ST to a color monitor other than Atari's. Recently, a ST model with the capability to connect to a conventional television has been announced, but I am more interested in using the ST with an RGB monitor.

One difficulty appears to be interlacing. Most monitors, based on TV conventions, use interlacing. The 520 ST apparently generates a non-interlaced video signal. Ordinarily, these two formats are incompatible, forcing the prospective ST owner to also purchase the Atari monitor.

Have I misunderstood some detail concerning interlacing? Does anyone have experience connecting an ST to a generic RGB or composite video monitor? Does anyone else care about connecting an ST to a monitor other than Atari's?

Mail sent to me will probably serve best, unless someone wants to make this an item for public discussion.

I agree with the previous letter about public domain programs. Although I probably won't use the C programming language, I am planning to write several programs which I will be happy to share with readers of the net.micro.atari users' group. I hope others have this attitude - if they do, we'll have some free, fun software floating around in no time!

I have almost no software for my 520ST, and I am in the market for a good compiler, word processor, LISP interpreter, telecommunication program, and drawing program, etc.

After my recent experience buying a C compiler for $60 that was a piece of trash (Hippo-C) I am reluctant to buy anything that I have not seen a review of.
The "lead time" of most magazines means that I will have to wait several months for reviews of obsolete versions of programs. Surely there are several of you in the net.micro.atari users' group that would be willing to share your impressions of 520ST software that you have used!

I would review software with some of the following criteria (you will have criteria of your own, certainly)

1. Name of program
2. What the program does
3. Is the program copy-protected (I almost refuse to buy protected software)
4. How extensive and useful is the program's documentation?
5. Price of program
6. From whom did you get the program
7. Does the program work as advertised?
8. Are there any significant bugs in the program?
9. Is source code available for the program?

    etc...

I hope some of you will review ST software soon (before I get burned again)

Thanks in advance,

    Your right, UNIX DOES need an MMU. I'll call Microsoft and H-P immediately
    and tell them to stop selling Xenix and HPUX because they can't possibly
    work. Boy are they going to be pissed. Oh well, they should have asked
    if they needed an MMU before they went ahead and ported UNIX to hardware
    that doesn't contain an MMU.

I couldn't reply directly (I tried twice), so the rest of you
please bear with me (& toss in corrections if I mess up).

1) As another msg has already said, copying the Action! cart
   is not something you want to publicly advertise for.

2) Aside from that, it's impossible. The Action! cart is a
   (32k?) bank selected "super-cart", meaning that there are
   seperate sections of the Action! system that try to run
   in the same address space (and can do so due to the bank
   selection scheme). You can't get that out into one binary
   file.

3) You might not have to create an autorun.sys to compile each
   time. Try compiling Kermit. Write it to disk as "kermit.tmp"
   Make a copy of your rs232 driver as autorun.sys & then use
   the dos C option to append the two files
   (C
    What files? (or something like that)
    kermit.tmp,autorun.sys/a
    (rumble... rumble... rumble....)
    D
    What files?
    kermit.tmp
)

    Now, you have the disadvantage of having to reboot the system
    each time you want to communicate, but you don't have to re-compile
    each time.

Good luck,

         -Richard Hartman

I have written, in assembly language, a simple graphics package for a 400/600
which waits for commands to come in from the serial bus (which is really a
modified RS232 interface).

I let the host computer simulate an Atari disk while the Atari powers up,
which allows the host computer to load a bootstrap program to the Atari.
This bootstrap is actually a graphics command handler, which "takes over" the
machine and monitors the serial bus for commands from the host.

I implemented a small set of graphics primitives (point draw, set draw color,
init screen, etc). I think the higher level graphics stuff is best done on
the host side in higher level language.

If you know something about 6502 code you might be able to modify this to
do what you want. If you are interested, call me at:

  615/574-5564 (tell secretary I said to forward the call or find me)
  615/691-7957 home, after 6PM EST

regards
  jim mullens

* Unix (TM) is a trademark of Bell Labs to describe the
absolutely wonderful operating system for programmers that
large segments of the computer industry have adopted not because
it is what they want but because it is portable. It also
describes the philosophy of those programmers whose goals in
designing Unix were to make a an operating system that would be
efficient and flexible to meet the needs of sophisticated users.

*                          A68 - MC68000 ASSEMBLER                          *
*****************************************************************************
```

(C) COPYRIGHT 1985 ROBERT G. BROWN
ALL RIGHTS RESERVED

A68 VERSION 1.0 PLACED IN THE PUBLIC DOMAIN WITH THE PROVISION
THAT IT NOT BE SOLD FOR PROFIT WITHOUT THE AUTHOR'S CONSENT.

A68 VERSION 2.0 IS PLANNED AS A COMMERCIAL RELEASE IN MID DECEMBER.
CONTACT THE AUTHOR FOR FURTHUR INFO.

A68 TAKES A STANDARD 68000 ASSEMBLY LANGUAGE SOURCE FILE WITH THE
EXTENSION .A68 AND PRODUCES A GEMDOS .PRG FILE.

THE COMMAND LINE TAKES THE FORM
A68 filename

THE SOURCE FILE SHOULD CONTAIN STANDARD 68000 ASSEMBLY LANGUAGE
AS DESCRIBED IN THE M68000 PROGRAMMER'S REFERENCE MANUAL.

EACH LINE TAKES THE FORM:
[label] opcode[.ext] [source],[destination] [comments] or
*[comments]

LABELS - must start in the first column with a letter. They are
valid to 6 characters and contain letters and digits. Lower case

letters are converted to upper case by a68. A label must be
follow by a white space character (TAB or SPACE).

COMMENT LINES - are indicated by a * in the first column.

OPCODE - must be preceded by white space. The ext is .b for byte
.w for word and .l for longword. If left out .w is assumed. The
branch instructions use .b and .w for short and long branch.

OPERANDS - must be prceded by white space and separated by a
comma. The addressing modes follow the standard as follows:

SP is not accepted in place of A7 or a7.

The absolute short addressing mode is not supported by GEMDOS.
Absolute long is assumed as the default unless .w is used as the extension.

The address register with displacement (with or without an index)
mode is treated as follows:
     d(An)   d is treate as an absolute displacement.

The program counter with displacement (with or without an index)
mode is treated as follows:
     d(PC)   d is treated as location to which a displacement
is calculated.

For the displacement with index modes the length of the index
must be specified by the .w or .l extension.

# indicates immediate data

$ indicates hex (i.e. #$ff is immediate data 255).

Only simple expressions are accepted by version 1.0. (no + - etc.)

THE FOLLOWING PSEUDO-OPS ARE SUPPORTED:

EQU
label EQU value
use the EQU to reference absolute memory locations. The locations
referenced by a EQU are not relocated by GEMDOS.

ORG
 ORG value
use only as the first opcode in a file to create an absolute file
without the GEMDOS relocation information.

DC.[ext]
 DC.B 'string',$hexvalue,decimalvalue etc.
defines constants of lenght .ext. Moves to next even address
after DC.B.

DS.[ext]

 DS.l value
reserves value number of locations of length .ext.

DCB.[ext]
 DCB.W count,value
defines constant value count number of times.

A68 ERROR MESSAGES ARE REPORTED AS THE SOURCE CODE IS DISPLAYED
ON THE CONSOLE IMMEDIATELY AFTER THE ERROR IN THE FORM <**En**>.

1 - Illegal opcode
2 - Duplicate label
3 - undefined label
4 - illegal operand
5 - illegal size
6 - branch out of range
7 - displacement out of range

THE SYMBOL TABLE IS LISTED AT THE CONCLUSION OF THE ASSEMBLY AND
A68 WAITS THE A SPACE BEFORE RETURNING.

IF YOU FIND A BUG PLEASE REPORT IT TO

Hi again,

when I wrote about the Action cartridge being put onto a diskette I
was more or less thinking of a one time use of Action simply to compile

some sort of Kermit self-booting alreaydy-compiled thing, not for Action itself. You all have helped changed my mind so I'll still use the cartridge for Kermit, but It sounds like a good language to learn.

I have a few questions about dialing into mainframes. In logging onto the 3081 mainframe here (cp/cms) everything I type is in uppercase until I hit the caps key (800XL) and then everything is in lower case. The only way to type words in uppercase is to hold down the shift key, because the caps key no longer sets it into capital letters. Does anyone know how to do this?

Also, when logging into a VAX/UNIX system here, MODEMLINK is interpreting something as slashes. For instance, /T/h/i/s/ w/o/r/d/ . How can I prevent this? Also, I haven't found a way to work mixed case from home, just upper case, though of course on the terminals here at weizmann I can.

That's all for this time...

Randy

Summary: How does the PC do it?

There are several implementations of UNIX-like operating systems, with multitasking, on the MMU-less IBM PC and compatibles. However it is done, it seems to be at least nominally compatible with UNIX. What methods are used here? Could they be applied to a 68000-based system? Am I missing the point entirely? (Perhaps PC UNIX's fork() does NOT act like real UNIX.)

Hope this is not the 1000th response on this topic. The Atari caps key
does not work like a typewriter shiftlock key. Hold down the shift key
and hit the caps key. That locks you into uppercase. Hit the caps key
without holding down shift and you are back to lower case again.

I believe the T/h/i/s /w/o/r/l/d is an attempt to show that you are
logged in in all upper-case mode and are typing lower case. Next time
log in in lower case and the /'s will disappear.

Dan

One good source of public-domain programs is Antic magazine. They have some
public-domain and low-cost programs that I'm certain to get (sorry, it's at
home so I can't give examples). Anyone who wants to do serious things with an
ST should subscribe to Antic and probably Analog as well.

It was from one of these magazines (Antic, I think) that I learned that the 520
ST has the ability to interrupt at the start of the horizontal and vertical
retrace intervals. In those intervals you can change things like the color
registers (which is what the example program did) and also, I hope, the
starting address for the bitmap. If you can change the bitmap's address on
every vertical retrace you can do really nice smooth scrolling. If you can
change it on every horizontal retrace as well you could provide (full-width
only) windows very efficiently.

Unfortunately, if the ST documentation tells you how to do this kind of thing I
haven't found it yet. I was rather annoyed that the hardware descriptions that
came with the developer's kit told me about the keyboard, the sound chip, the
DMA chip, and the diskette driver chip, but not a word about the display chip.
Have later developer's kits remedied this problem? Or is the information
buried somewhere I haven't found yet?

If a body is in low Earth orbit will the surfaces of the object become charged by triboelectric effect from collisions with the molecules that are present, albiet scattered & few in number compared to atmosphere, in the space it passes through ? Is there a reasonable guess as to the charge level that might result. I expect that there might be some equilibrium level that would be reached, but that is just a guess.

I would like to clear up a common misconception about ACTION!. You don't need the ACTION! cartrige in order to run programs written in ACTION!. If you have the ACTION! runtime package (about $30 from O.S.S.) then you can compile ACTION! programs into binary files which can be run directly from DOS. However, if you do not have the run time package then you will need the cartrige to run the programs.

Can anyone tell me how I can get a simple timer tick on my ST? I need a
high resolution timer so that I can record keystrokes off of MIDI for a
simple sequencer I'm writing. However, I've looked through all the
developer documentation and can't figure out how to do it... Do I have to
write an interupt handler to count timer interupts? (ugh...) I can't believe
it's as hard as that...

Could someone provide me with the details of becoming

a software developer for the 520 ST, please?
Thanks much,
John

I am forwarding these instructions to the net as the original
author does not have access to usenet. So far he and I as far as
I know are the only ones who have upgraded to 1 meg. If you are
brave enough to try this upgrade you might want to let us know
if you succeeded or perish the thought failed.

-ravi

From: Gert Slavenburg <gert@Pescadero>
Subject: manual to 520ST 1 Meg upgrade
To: info-st@eneevax
Status: RO

I had enough requests to justify sending this out to all of you at info-st.
Good luck with the modification. Cheers will be appreciated, as well as
examples of use of the full 1 Meg - it's lonely at the top.

Directions for expanding the Atari 520ST memory to 1 MByte
==========

WARNING : This is a hardware modification that will void the warranty of
your 520ST. If you do not have the appropriate tools or experience you
have a substantial chance of ruining your 520ST. Proceed at your own risk !
This modification has been in my 520ST without any problems for 6 days now.
However, I have (of course) not checked with knowledgable sources at Atari
to verify if this modification endangers the long term machine reliability
and/or software compatibility (I suspect it may endanger their software
compatibility if enough of us do it !).

tools/components needed :
==========

16 256k * 1 RAM chips, 150 nSec. access time type, e.g. NEC 41256C-15.
(available at e.g. Fry's Electronics, Sunnyvale, CA for $ 2.77 each)

A good quality, preferrably temperature controlled soldering iron, with
a miniature tip (tip should be narrow enough to avoid touching 2 I.C. pins
at the same time). E.g. Weller type soldering station.

Good quality resin core solder (thin).

Approximately 4 foot of wire-wrap wire and a good stripper for it.
(you will have to route 3 wire's over a sequence of I.C. pins. The
easiest way to do this is to have a stripper allowing you to shift the
isolation forward over the wire, solder the next point, measure new length,
shift over insulation etc. until the endpoint). The "No Nik" .014" (dark
green handle) wire wrap stripper is the best tool for this. Available
e.g. at Jensen tools, Phoenix, AZ (602) 968-6231 catalog no H4B305.

De-soldering wick and solder suction tool.

Philips type screwdriver (for opening your ST), tweezers, pliers etc.

A steady hand and self-confidence.

explanation of the modification :
==========

(Please read the rest of this document before starting. It may save you time and a 520ST)

The current memory inside the 520ST consists of 16 256k*1 RAM chips.
Address (A0..A8) lines are common to all those chips.
The WriteEnable line is also common to all chips.
Data (in and out) lines are (of course) individual. The RAS (Row-Address Strobe) line is common to all chips. The 8 chips forming the high order byte group have one common CAS line, and the 8 forming the low order byte group have one common CAS line (CAS is used as enable for write operations, suchthat WriteEnable can be common to both groups).
The high order group from MSB to LSB consists of U45,44,43,42,38,34,33,32.
The low order group of U30,29,28,25,24,18,17,16. Note that all chips are adjacent, though the numbering has gaps. RAS0, CAS0H and CAS0L are supplied from U15 pin 8,6 and 7 respectively. (The 0 indicates bank 0)

Bank 1 that you are going to build in will be "piggy-backed" on top of the current chips, where all pins of the new chips EXCEPT RAS (pin 4) and CAS (pin 15) are soldered to the old chips equivalent pin. Thus they will end up sharing addresses, data, WriteEnable and power and ground with the existing chips.

All RAS pins of the new chips are wired together and will be supplied with the "RAS1" signal generated on pin 18 of U15 (the Memory Controller, marked 3H-2119CC or so).
The CAS pins of the 8 new high order byte chips (on top of U45..U32) are wired together and supplied from the "CAS1H" signal generated on pin 22 of U15.
Analogously, the CAS pins of the new U30 to U16 are wired together and supplied with "CAS1L" from pin 21 of U15.

how to go about it :
==========

step 1 : Open up your 520ST, pull of the keyboard connector, and remove the main circuit card from its top and bottom shielding. Make sure to remember which screws go where and note the keyboard connector orientation.

step 2 : Desolder all the capacitors adjacent to the existing RAM chips. (DO NOT SKIP THIS STEP. You'll loose time if you do, and worse, the modification will not be reliable since you can't solder the pins obstructed by the capacitors reliably (if at all)). To desolder them, I found it easiest to heat the island on the non component side, and bend the wires straight. After doing that for each capacitor, turn over to the component side and heat the islands while pulling the capacitor out with tweezers.

step 3 : Open up the holes of all the desoldered capacitors, using a combination of de-soldering wick and suction tool. Do this from

the non-component side. If certain holes are difficult to open up, you may want to use a wood splinter. (push it through while heating). Be carefull to remove all solder debris !
THE REASON for opening the holes NOW is that they will be less accessible once you've done the other steps ! Patience is a virtue.

(NOTE : Step 2 and 3 are the only ones that may damage your ST PCboard. Be sure not to use excessive force while pulling out the capacitors. If you damage your PCboard anyway, cure the problem now and not later).

step 4 : In this step we will piggyback the new RAM's on top of the old ones. Be sure to connect all pins except pin 4 (RAS) and 15 (CAS).
The best way to go about this is to do chip by chip. First bend the pins of the new RAM's suchthat they are perpendicular to the package (instead of having slightly spread "cowboy legs"). Use pliers to bend pin 4 and 15 suchthat it comes out of the I.C. package horizontal, and cut of the excess length of pins 4 and 15 (I mean part of the pin, you still need to be able to solder to it!). Make sure that the new RAM fits snugly on top of the old one (in the same orientation !!!!), without intervening space and with the new pins touching the old ones. Now solder
each pin (except the non-touching 4 and 15) to the other RAM's.
The best way to do this with least chance of damage is to touch both the new RAM's pin and the old RAM's pin. Heat them both for a second and add A LITTLE solder then. Wait till the solder flows.
After each IC, check all pins carefully to assure a good connection. (use a magnifying glass)
NOTE : This step is crucial for the long term reliability of the memory extension. A badly soldered joint may show up later as sporadic memory errors. TAKE YOUR TIME.

(NOTE : until step 6 is finished, do not in any way apply power to your ST. This intermediate state of affairs will damage your memory chips !)

step 5 : Re- mount all the desoldered capacitors. Bend the pins like they were before re-soldering, suchthat they will not touch the lower shielding. Solder from the non-component side.

step 6 : In this step you will route the 3 wires mentioned earlier. The first wire connects pin 4 (RAS) of all new RAM's to pin 18 of U15. The second wire connects pin 15(CAS) of the new U45 to U32 to pin 22 (CAS1H) of U15. The third wire connects pin 15 (CAS) of the new U30 to U16 to pin 21 of U15.
The best way to do this is to use the stripper to remove 5 inches of isolation. Solder the first IC pin to the end of the blank wire, measure the distance to the next pin in sequence and shift over that amount of isolation. Continue in this fashion untill all pins in the sequence are done.
Work from U45 to the left, soldering directly to the leftover pins on the new chips. Make sure that no wire or solder sticks out above the top plane of the new chips, since they will almost touch the top shielding !
Route the wires through the PC board hole below and to the left

of U15 to connect to U15 on the non-component side.

step 7 : Sit back. Use brain. Do you feel confident about the quality of
your work ? No mistakes ? Check everything once again if you are
but a little uncertain. Applying power with errors might make your
ST into a decorative, non-functional piece of art.
OK. Either rebuild your ST into its shielding and cabinet, or put
it onto a surface clear of wires and solder-remains and connect it
to monitor, disk and supply. Boot it.

If it boots, you're probably there. Test if the new memory works
by looking at the phystop variable ($42E) with SID if you have the
developper stuff. It should read $100000 (1M hex). Also note that
memcntlr ($424) now holds 5 instead of 4, and that v_bas_ad ($44E)
now holds $F80000 (screen bitmap origin).
If you don't have the developper stuff, try a single drive copy and
check that you get the whole disk in one buffer instead of two.

If the new memory does not seem to exist, use SID to deposit and
retrieve words on locations $80000 and up (1/2 M hex). If bit errors
occur, the ST bootROM did not detect the extension (it checks all
bits of 512 locations by testing a pseudo random sequence, before
accepting a memory bank). Try to pinpoint the faulty chip(s) and
remove the error.

If it doesn't boot, you're in trouble. I'm sorry. It is difficult
to give hints on what to do here. So many possibilities.
Desoldering the new chips probably won't work (if the old ones
were functional, the ST would still boot). Check for hidden
short-circuit on RAM pins. May also be that you have a flaky
new pin connection.
Good luck. I feel bad. Well, I might be able to help you a little,
call me when you're really stuck ! Evenings at (415) 965-7696.
Not after september - I'll be out of USA by then.

PLEASE :
========

Let me know if you did the modification and failed or succeeded. I'd like
to know how many people benefit from this and if it's safe enough for large
scale application. Mail to arpanet address gert@su-pescadero.

> UUCP: ...{decvax,ucbvax}!decwrl!imagen!turner

After reading the above article, I downloaded the revised procedure from Compu Serve. I have had the upgrade for about 3 months, and has worked without a flaw. I would have probably added the proms without the resistors. Thanks to Mr. Turner for the warning.
Here is a copy of the revised procedure:

NOTE: This is an REVISED,TESTED version of the original text downloaded from CompuServe. December 6, 1985

(This was REVISED AND TESTED by an annonymous engineer on Atari's developement staff. The addition of the resistors should provide a long life to your machine, but the warning below is STILL IN EFFECT. This is not an official sanction of the modification. USE WITH CARE!!!)

Here's the 1 Meg upgrade directions:

I have brought this over un-editted from the arpanet info-st mailing list. I TAKE NO RESPONSIBILITY FOR ITS CONTENT OR ACCURACY. I HAVE NOT TRIED THIS MODIFICATION ON MY OWN ST AS YET. I AM PASSING THIS ALONG TO THOSE WHO DO WISH TO TRY IT. FOLLOW THE DIRECTIONS AT YOUR OWN RISK.
--Dwight McKay (75776,1521)

From: gert@pescadero

WARNING: This is a hardware modification that will void the warranty of your 520ST. If you do not have the appropriate tools or experience you have a substantial chance of ruining your 520ST. Proceed at your own risk! This modification has been in my 520ST without any problems for 6 days now. However, I have (of course) not checked with knowledgable sources at Atari to verify if this modification endangers

the long term machine reliability and/or software compatibility (I suspect it may endanger their software compatibility if enough of us do it!)

Tools & components needed :

16 256k * 1 RAM chips, 150 ns access time type, e. g. NEC 41256C-15 (avilable at e. g. Fry's Electronics, Sunnyvale, CA for $2.77 each)

A good quality, preferrably temperature controlled soldering iron, with a minature tip (tip should be narrow enough to avoid touching 2 I. C. pins at the same time). E. g. Weller type soldering station.

Good quality resin core solder (thin).

Approximately 4 foot of #24 AWG insulated wire and a good stripper for it and 2 feet of #22 AWG solid tinned copper bus wire. You will have to route 3 wires over a sequence if I.C. pins.

Desoldering wick and solder suction tool.

Philips type screwdriver (for opening your ST), tweezers, pliers, etc.

A steady hand and self-confidence.

Explaination of the modification :

(Please read the rest of this document before starting. It may save you time and an 520ST)

The current memory inside the 530ST consists of 16 256K*1 RAM chips. Address (A0..A8) lines are common to all those chips. The WriteEnable line is also common to all chips. Data (in and out) lines are of course individual. The RAS (row-address strobe) line is common to all chips. The 8 chis foring the high order byte group have one common CAS line, and the 8 forming the low order byte group have one common CAS line (CAS is used as enable for write operations, such that WriteEnable can be common to both groups). The high order group from MSB to LSB consists of U45, 44, 43, 42, 38, 34, 33, 32. The low order group of U30, 29, 28, 25, 24, 28, 27, 26. Note that all chips are adjacent, though the numbering has gaps. RAS0, CAS0H, and CAS0L are supplied from U1 pin 8,6 and 7 respectively (The 0 indicates bank 0)

Bank 1 that you are going to build in will be "piggy-backed" on top of the current chips, where all pins of the new chips EXCEPT RAS (pin 4) and CAS (pin 15) are soldered to the old chips equivalent pins. Thus they will end up sharing

addresses, data, WriteEnable and power and ground with the existing chips.

All RAS pis of the new chips are wired together and will be supplied with the "RAS1" signal generated on pin 18 of U15 (the memory controller, marked 3H-2119C or so). The CAS pins of the 8 new high order byte chips (on top of U45..U32) are wired together and supplied from the "CAS1H" signal generated on pin 22 of U15. Analogously, the CAS pins of the new U30 to U16 are wired together and supplied with "CAS1L" from pin 21 of U15.

How to go about it:

Step 1: Open up your 520ST, pull off the keyboard connector and remove the main circuit card from its top and bottom shielding. Make sure to remember which screws go where and note the keyboard connector orientation.

Step 2: Desolder all of the capacitors adjacent to the existing RAM chips. (DO NOT SKIP THIS STEP. You'll lose time if you do, and worse, the modification will no be reliable since you can't solder pins obstructed by the capacitors reliably (if at all)). To desolder them, I found it easiest to heat the island on the non component side, and bend the wires straight. After doing that or each capacitor, turn over to the component side and heat the islands wile pulling the capacitor out with the tweezers.

Step 3: Open up the holes of all the desoldered capacitors, using a combiation of de-soldering wick and suction tool. Do this from the non component side. If certain holes are difficult to open up, you may want to use a wood splinter. (push it through while heating). Be carefull to remove all solder debris!! THE REASON for opening the holes NOW is that they will be less accessible once you've done the other steps! Patience is a virtue.

(NOTE: Step 2 & 3 are the only ones that may damage your ST PC board. Be sure not to use excessive force while pullling out the capacitors. If you damage your PC board anyway, cure the problem now and not later).

Step 4: In this step we will piggyback the new RAM's on top of the old oes. Be sure to connect all pins except pin 4 (RAS) and 15 (CAS). The best way to go about this is to do chip by chip. First, bend the pins of the new RAM's suchthat hey are perpendicular to the package (instead of having slightly spread "cowboy legs"). Use pliers to bend pin 4 and 15 such that the legs are 180 degrees from their normal position, so they stick up in the air above the plane of the top surface of the chips. Don't make an absolute sharp 180 degree bend since some manufacturers' pins may snap off.

Leave a little curve in the leg, but insure that is above the plane of the top surface of the chip.

Using #22 AWG to #16 AWG tinned solid copper wire you will form three buses along the top surface of the new d-rams. Cut a #22 AWG solid copper wire the length of the 16 d-rams on the PCB. The RAS bus is formed by soldering all the pin 4's of the new d-rams to the solid copper wire. The bus wire must be seated against the top surface of the new d-rams without a gap. This insures clearance between the top shield and the pins of the d-rams.

After soldering all 16 d-rams to the bus clip off any portion of the pins that extend above the top of the bus wire. Now cut a #22 AWG solid copper wire the length of the 16 d-rams. Place the bus wire along the top surface of the new d-rams in contact with all the pin 15's of the new d-rams. Solder every pin 15 to this bus and as above insure that the wire is seated solidly against the top surface of the new d-rams. Cut off all excess pin length sticking up above the top of the bus wire. Using diagonal cutters remove the section of the bus connecting the new U30 pin 15 to the new U32 pin 15. This divides the bus in half with the new U16, 17, 18, 24, 28, 29 having a common pin 15. The new U32, 33, 34, 38, 42, 43, 44, 45 now have a common pin 15, seperated from the other common bus.

(NOTE: until step 6 is finished, do no in any way apply power to your ST. This intermediate state of affairs will damage your memory chips!!)

Step 5: Remount all the desoldered capacitors. Bend the pins like they were before resoldering, suchthat they will not touch the lower shielding. Solder from the non component side.

Step 6: Orient the 520ST PCB so that you are looking at the solder side of the PCB (non-component side), with the row of d-rams nearest you. Find the double square pattern of pads at the 68-pin socket of the memory controller, U15 (3H2119). The following is a guide to locating the six memory controller pins necessary to complete the wiring. The socket is numbered conterclockwise, starting with pin 1, the square pad (look closely) in the middle of the bottom outside row. The sequence, moving counterclockwise from pin 1, first on the outside square ONLY: (NOTE: the sequence ")(" means to make a 90-degree turn counterclockwise, i.e. around the corner)

1,3,5,7,9)(10,12,14,16,18,20,22,24,26)(27,29,31,33,35,37,39,41,43)(44,46,48,50,52,54,56,58,60)(61,63,65,67

The sequence, moving counterclockwise along the inside

square only, and starting with the left side of the bottom row:

(62,64,66,68,2,4,6,8)(11,13,15,17,19,21,23,25)(28,30,32,34,36,38,40,42)(45,47,49,51,53,55,57,59)

Six 68-ohm 1/4W plus/minus 10% carbon film resistors must be added when adding memory. These series terminating resistors minimize undershoot which may damage BOTH BANKS of d-rams if omitted. Solder a 68-ohm resistor to pin 18 of U15, RAS1. Solder a #24 AWG stranded wire from the remaining end of the 68-ohm resistor to the pin 4 bus (RAS) of all the new d-rams. that is the new U16, 17, 18, 24, 25, 28, 29, 30, 32, 33, 34, 38, 42, 43, 44, and 45.

Solder a 68-ohm resistor to pin 22 of U15, CASH1. Solder a #24 AWG stranded wire from the remaining end of the 68-ohm resistor to pin 15 bus (CAS) of the new U45,44,43,42,38,34,33,32.

Solder a 68-ohm resistor to pin 21 of U15, CASIL. Solder a #24 AWG stranded wire from the remaining end of the 68-ohm resistor to pin 15 bus (CAS) of the new U30, 29,28,25,24,18,17,16.

For best results in all three cases above solder the wires coming from the resistors to the middle of the three bus wires in a "T" fashion rather than at one end of the buses.

Use a continuity tester to find the following three traces -- do not depend on visual inspection. Now install three 68-ohm series terminating resistors in the original 512K bank of ram. Be very careful while soldering to these narrow traces, since excessive heat can easily lift a trace from the board. Use an Exacto knife to gently remove solder mask from traces.

Cut the trace leading from pin 8, RAS0, of U15 near U15. Solder a 68-ohm resistor in series with the trace.

Cut the trace leading from pin 6, CAS0H, of U15 near U15. Solder a 68-ohm resistor in series with the trace.

Cut the trace leading from pin 7, CAS0L, of U15 near U15. Solder a 68-ohm resistor in series with the trace.

Step 7: Sit back. Use Brain. Do you feel confident about the quality of your work? No mistakes? Check evrything once again if you are but a little uncertain. Applying power with errors might make your ST into a decorative, nonfunctional piece of art. OK. Either rebuild your ST into its shielding and cabinet, or put it onto a surface clear of wires and solder remians and connect it to monitor, disk and supply.

Boot it.

It it boots, you're probably there. Test if the new memory works by looking at the phystop variable ($42E) with SID if you have the developer stuff. It should read $100000 (1M hex). Also note that memcntlr ($424) now holds 5 instead of 4, and that v_bas_ad ($44E) now holds $F80000 (screen bitmap origin). If you don't have the developer stuff, try a single drive copy and check that you get the whole disk in one buffer instead of two.

If the new memory does not seem to exist, use SID to deposit and retrieve words on locations $80000 and up (1/2 Meg hex). If bit errors occur, the ST bootROM did not detect the extension (it checks all bits of 512 locations by testing a psedo random sequence, before accepting a memory bank). Try to pin point the faulty chip(s) and remove the error.

If it doesn't boot, you're in trouble. I'm sorry. It is difficult to give hints on what to do here. So many possibilities. Desoldering the new chips probably won't work (if the old ones were functional, the ST would still boot). Check for hidden short:circuit on the RAM pins. May also be that you have a flaky new pin connection.

That's all there is...

||what about all the relocation fancy footwork that unix does
||to handle the per process data area
|< Lots more "reasons" that UNIX needs an MMU >
||simon kenyon
|Your right, UNIX DOES need an MMU. I'll call Microsoft and H-P immediately
|and tell them to stop selling Xenix and HPUX because they can't possibly
|work. Boy are they going to be pissed. Oh well, they should have asked
|if they needed an MMU before they went ahead and ported UNIX to hardware
|that doesn't contain an MMU.

Is it possible that you stop this fruitless discussion about whether
'UN*X' (whatever that means) needs an MMU (whatever that means)?

Yes, there are operating systems out there that you can call UN*X
and that get along without an MMU. Yes, none of the Berkeley versions
of UN*X will run comfortably without an MMU (although, as Berkeley
shows again and again, blind hacking can achieve anything, even if
it crashes all the time and is incredibly slow...).

One concluding remark: the 8086 (without an MMU) is probably more
suited to running UN*X than the 68000 without an MMU. The reason for
this is that the segmentation of its address space gives you some
kind of rudimentary memory management. You can, in principle, do
the same thing on the 68000 using indexed addressing and PC relative
addressing, but you sacrifice a lot of the power of the 68000 that
way.

Now, you all who claim that you can make a UN*X run on the ST would
do everybody a great service if you carried out what you claim is
possible. Failing that, I am personally eagerly awaiting OS9.

                              Thomas.

     An operating system that is "not...what [large segments of the computer industry] want" is not "absolutely wonderful." Nor is it "efficient", since Unix systems typically spend about 50% of the CPU in the operating system. One questions the flexibility of an operating system which lacks file locking, record structure, and shared writeable pages -- granted these are now being shoehorned into Unix, but they should have been in there from the beginning.

     Are you aware that Dennis Ritchie once said that if he had known about Tenex, he never would have invented Unix? The goal in designing Unix were to create an quick and dirty operating system on a discarded PDP-7 so a group in Bell Labs (which had been denied their purchase request for a newer and large CPU) could get some work done.

     Has everyone seen page 34 of Tuesday's New York Times?
     "Last week Atari said it was pulling its new 520 ST out of computer
retail stores, where it fared poorly, and was moving it to mass-market
channels.
     At the Consumer Electronics Show in Las Vegas, Nev., later this
week, Atari is expected to introduce a new more powerful version of the
computer for the computer speciality stores."
     Even gloomier comments are made about the Amiga's sales:
     "They would have been lucky to get rid of 35,000."
     "What crippled Amiga sales...."
     etc.

I did the 1meg upgrade, and so far everything is working fine. I have

not installed the TOS ROMs. I used the method that involved adding 6
68 ohm resistors. A side note: with the additional memory I have
made extensive use of the RAM DISK (from Michitron) and have encountered
something I can not explain. After some random amount of compiling, editing,
and copying of files to the RAM DISK something happens in which I can no
longer access my floppy drives A and B. Anyone else encountered something
like this ???

I have only been moderating INFO-ATARI for a month or so. My observations may be flawed. But let me add them to the attached.

Mail re-distributed by SU-SCORE's mailer on behalf of INFO-ATARI sometimes gets the field ERRORS-TO:INFOR-ATARI-REQUEST@SU-SCORE added to the header. I think that SCORE is the only entity that knows about this address, so that is where the addition occurs. It occurs to mail sent from more sites than ucbvax. I suspect that it depends on the original host mailer's sequence of header lines.

The purpose is to reduce the amount of error messages annoying original contributors. INFO-ATARI-REQUEST is the official address to which all requests for addition and deletion from the list should be sent. It is also the only location where somebody can take action on complaints from mailers about hosts not reachable, individual users unknown, etc.

I hope this adds to the general state of knowledge.

Return-Path: <@SRI-BISHOP.ARPA:TYSON@SRI-AI.ARPA>
Received: from SRI-BISHOP.ARPA by SU-SCORE.ARPA with TCP; Wed 8 Jan 86 13:47:29-PST

cc: info-atari-request@SU-SCORE.ARPA
Fcc: SRI-WARBUCKS:USR:[TYSON.MAIL]MYMAIL.MAI
In-Reply-To: <171@imagen.UUCP>
Message-ID: <860108135031.4.TYSON@SRI-BISHOP.ARPA>

I apologize. I had thought a whole bunch of people had seen the ERRORS-TO: field and were doing it themselves. Apparently it was being done without your knowledge.

Judging by the message you just sent, your host imagen talks directly to ucbvax. Then ucbvax talks to SCORE which then sends it to me at SRI-AI.

The Arpa protocols are pretty clear about what happens to message headers and such. The UUCP guys like to get in and "fix" your message (by changing the addresses deep within the header). So I suspect that someone hacked ucbvax to add the Errors-To field if it is a message to INFO-ATARI.

I just noticed that, horrors upon horrors, the ucbvax people really screw it up and put the RETURN-PATH to be info-atari-request@SU-SCORE !!! When I get mail that has come through ucbvax I get notified that it was sent by INFO-ATARI-REQUEST@SCORE. (The RETURN-PATH in the internet world is supposed to be the God's truth of how to get back to the sender. After all, the sender can put whatever he wants in the FROM: field. Each host along the way is

supposed to put in all the info to get back through him back to the previous host. So for a message from you to me via INFO-ATARI, the return path should have been
     <@SU-SCORE.ARPA:imagen!turner@UCBVAX.BERKELEY.EDU>
but is actually
     <@SU-SCORE.ARPA:info-atari-request@SU-SCORE.ARPA>.

It is my opinion that the postmaster at UCBVAX should fix this failure to follow Arpanet protocols. If I were postmaster at SCORE or the moderator for INFO-ATARI, I would point this out to him (postmaster@ucbvax).

I also apologize because when I (just today) sent in about 3 requests for address changes, I realized how automatic it was to type just the name of the mailing list and not include the -REQUEST part.

I am also concerned a little that some of the readers of INFO-ATARI may think that our glorious moderator was responsible for that message. If there is any more discussion of this on the whole list, please mention that it was not he. You should feel free to say it was me that sent that message. I kinda hate to send out a message just to say it was me and not the moderator but will gladly do so should either of you desire.

Regarding the 1MEG upgrade of the 520ST, the European 1040ST is simply a piggybacked 520ST but there are no resistors in the RAS and CAS lines and they seem to be reasonably reliable even with TOS in ROM (according to my source). So why do Americans need the resistors? One theory: some, but perhaps not all, of the upgraders have damaged their DRAMs in some way when installing them and the resistors allow these DRAMs to function or prevent

further damage.

Further note: it has been said that the critical period for 1MEG upgrades
is between 3-5 months after the change (if anything will happen it usually
will happen then - assuming, of course, that the modification was successful
initally). So, if you made the upgrade without the resistors and have not
gone back to put the resistors in (perhaps because everything is fine with
your system) and it has not been 5 months since you did the upgrade it might
be wise to go back and do so. Adding the resistors shouldn't hurt performance
of the ST and may prevent you from damaging your DRAMs later.

With the cooperation of the SU-SCORE systems staff, the INFO-ATARI
archives have been moved and made more accessable.
They are now in <BBOARD>ATARI.*. This way, in addition to
being the archives, they can be read as a bboard by Score users.

All of the old archives were copied there too. From now on,
ATARI.TXT will get pruned automatically (to ATARI.date) whenever
it gets too large (over about 250 tops20 pages).

The current contents of the archives are as follows:

```
   PS:<BBOARD>

There seems to be alot of anxiety about putting the 520ST into
the Mass market.  At first it looks like Atari is pulling the rug
out from under its dealers.  This is simply not true.  You see
Atari IS NOT LOWERING THE PRICE OF THE ST, but is simply selling
it unbundeled.  Actually if you bought the Total system from
a mass marketer you would not save a single penny.  Actually
this move by Atari is good news for dealers, because there will
be even a bigger base to sell monitors, drives, software, etc..
Also Atari dealers will soon be selling Personal Mini-Computers in
the near future, which will have a better profit margin for its
dealers. Yes Mini Computer not Micro computer

**********just in case something gets the munchies**********

There have been a number of comments concerning Atari selling the ST in general merchandise stores at a lower price than in the computer specialty stores. Some have stated that this makes the 520ST a 'toy' computer. Others have said that it will irritate the computer specialty stores but that doesn't matter because we don't need them anyway. I disagree with both points of view. Where something is sold does not determine its quality. And, the computer specialty stores are as much a part of the computer industry as are the hardware manufacturers and software developers. Whether the computer specialty stores will be irritated by this new development depends on what Atari gives them in compensation. If this change in merchandising policy is handled correctly by Atari, it should benefit software developers and computer specialty stores alike.

You can develop gigabytes of software, but, if there is no one to buy it, what is the point? Atari sold the ST in specialty stores at the lowest price it could to build a base of developers and cash flow. Apparently Atari is satisfied that they can now go on to the next stage in marketing their product. By selling in general merchandise stores at a lower cost, Atari makes the product available to home users (as opposed to developers). These people want machines with software; they don't want to pay a lot for them. If the machines sell in the quantity one would expect from the quality and price, an enormous consumer base will be established for the developers' software, and the even greater cash flow will allow prices to remain low. This will mean more money in everyone's pockets and an enormous library of off the shelf software for *all* ST owners.

Now to the specialty stores. Specialty stores whether they sell computers, cars, furniture, or whatever are staffed by salespeople. Often salespeople are pushy and many don't know as much about the product they are selling as as one would expect. However, we can hope that the people who have given the computer specialty stores a bad reputation are increasingly in the minority. Specialty stores stock a much wider assortment of whatever their specialty is than do mass market general merchandise stores. A furniture store doesn't sell just one type of couch; a computer specialty store doesn't just sell one printer or one modem. By specializing in computer equipment, the computer store can afford to carry a wide selection of software, a number of printers, a number of modems, and, yes, a number of computers. The best stores have training and consultation services that do help the buyer. They compliment the general merchandisers by offering a wider range of goods and services. Whatever else might be said about the specialty stores they sell variety. (And, no, I do not work, and never have worked, as a salesman for computers or anything else.) If there weren't computer specialty stores (including mail order firms), the choices for all users would be severely limited. They provide the market that allows machines like the Atari to be developed and sold. In addition, computer specialty stores provide the cachet needed to enter the business market. Businesses like to deal with specialty stores because of the variety they offer, the expertise that is available from the best stores, and, since most businesses specialize, the fact that these stores specialize. Needless to say sales to the business community are nice to have.

So why undercut the computer specialty stores? The article I read in "USA Today" (12/27/85) did not make it seem like the specialty stores would be undercut by the prices of the general merchandise stores. Rather, it stated that the current version of the 520ST would be sold for an *undisclosed* lesser amount in the general merchandise stores and that a 1 megabyte version would be sold through the specialty stores at the current price ($799 mono; $999 color). We all know that a knowledgeable person can do the upgrade to 1 meg for under $50; so either the discount to the general merchandisers will be minimal, or the specialty stores will have to be offered something else to make their version of the product more attractive. I have heard rumors that a DSDD drive would be bundled with the 1 meg ST in the specialty stores. (Confirmation or other rumors would be appreciated.) Since the double sided drive retails for about $100 more than the single sided drive there might be some room for play here. With the volume sales coming from the general merchandisers, Atari might be able to eat this cost and allow the specialty stores to sell the 1 meg ST with the DSDD drive for the same price as, or at a nominal increase from, the current 520ST. At the same time, specialty stores are going to carry greater varieties of software and be the likely merchandisers of higher priced add-ons such as hard disks and CD ROMs.

Of course there are a number of people, many of them developers, that have already bought 520ST's for $799 or $999. If this change in marketing policy by Atari is going to work, these people will have to be appeased also. If the dealers are going to get a 1 meg ST for the same cost as the 520ST the current owners should be provided the upgrade at no, or minimal, cost. And, if a DSDD drive is put in the dealers package, current owners should be able to trade up to the DSDD drive or in some way be compensated. This appeasement is necessary, I think, because many of the current owners are developers. Sales through the

general merchandisers depend on software being available. Software depends on those developers; so the developers have to be kept happy.

   In conclusion, if this marketing change is handled properly, it will benefit everyone. If it isn't, *then* the ST may become a toy computer. Let's limit further discussion on this topic to facts, rumors, and titilating speculation. Puerile and sophomoric comments about machines of whatever persuasion should either be sent to net.flame or kept to oneself.

Just a little correction to an otherwise fine article. The Action! cartridge
is actually a 16k bank selectable cartridge. It uses only 8k of ram at any
one time. It would be very difficult to duplicate because of the hardware
inside the cartridge that does the bank selection.

ray's my name Action's! my game.

NOOOOOOOOO!!!!! unless you REALLY know what you're doing use a
plastic tool designed (avail at radio shack etc.) for just this
purpose. sticking a metal screw driver into a TV monitor is a good
way to light up your life but good.

That Vert. Line. stands for Verticle *Linearity* and simply establishes the proportion of spacing between lines of scan top relative to bottom. The effect is to make possible *TALLER* char's at the top and decreasing in height in each line closer to the bottom (or vice versa). The Vert. Ht. increases the spacing between ALL lines (or decreases). If you do this adjustment without pro-portionately adjusting the Horiz. Width of the scan, you get the stretched up display described. **For safety's sake, please use a plastic screwdriver to make this adjustment; metal blades can result in an electrifying experience**

In article <12173670725.8.MRC@PANDA> you write:
>
>   An operating system that is "not...what [large segments of
>the computer industry] want" is not "absolutely wonderful." Nor
>is it "efficient", since Unix systems typically spend about 50%
>of the CPU in the operating system.

   Who cares? CPU time is cheap, programmer time is not.

>One questions the flexibility
>of an operating system which lacks file locking, record structure,
>and shared writeable pages -- granted these are now being shoehorned

>into Unix, but they should have been in there from the beginning.

   Why should they have been in there since the beginning? Some of the
   most powerful database systems in existence run under UNIX. They seem
   to get by just fine. What type of record system would you like? One
   like VMS, one like RSX, one like MACE? And what happens when you
   want to move software between the systems? Some people feel that these
   type of things do not belong in an operating system; I am one of them.

>
>   Are you aware that Dennis Ritchie once said that if he had
>known about Tenex, he never would have invented Unix?

    So?
>The goal in
>designing Unix were to create an quick and dirty operating system
>on a discarded PDP-7 so a group in Bell Labs (which had been denied
>their purchase request for a newer and large CPU) could get some work
>done.

   And the Greeks invention of geometry was so that they could settle
   land disputes. That doesn't make the invention of geometry any less
   significant: "Necessity is the mother of invention." That's not
   original, but it is relevant.

Hear, Hear. I would think that the people on the net who do not need the hand-
holding and advice of someone who knows less than them, Computer store salesman,
would welcome the opportunity to get the best deal possible. Are you guys
against a good deal?! Since Atari makes the development kit available, then the
money you save can be spent on it. Making it cheap *AND* easy to use.

After reading the above article, I downloaded the revised procedure from Compu Serve. I have had the upgrade for about 3 months, and has

worked without a flaw. I would have probably added the proms without the resistors. Thanks to Mr. Turner for the warning.
Here is a copy of the revised procedure:

NOTE: This is an REVISED,TESTED version of the original text downloaded from CompuServe. December 6, 1985

(This was REVISED AND TESTED by an annonymous engineer on Atari's developement staff. The addition of the resistors should provide a long life to your machine, but the warning below is STILL IN EFFECT. This is not an official sanction of the modification. USE WITH CARE!!!)

Here's the 1 Meg upgrade directions:

I have brought this over un-editted from the arpanet info-st mailing list. I TAKE NO RESPONSIBILITY FOR ITS CONTENT OR ACCURACY. I HAVE NOT TRIED THIS MODIFICATION ON MY OWN ST AS YET. I AM PASSING THIS ALONG TO THOSE WHO DO WISH TO TRY IT. FOLLOW THE DIRECTIONS AT YOUR OWN RISK.
--Dwight McKay (75776,1521)

From: gert@pescadero

WARNING: This is a hardware modification that will void the warranty of your 520ST. If you do not have the appropriate tools or experience you have a substantial chance of ruining your 520ST. Proceed at your own risk! This modification has been in my 520ST without any problems for 6 days now. However, I have (of course) not checked with knowledgable sources at Atari to verify if this modification endangers the long term machine reliability and/or software compatibility (I suspect it may endanger their software compatibility if enough of us do it!)

Tools & components needed :

16 256k * 1 RAM chips, 150 ns access time type, e. g. NEC 41256C-15 (avilable at e. g. Fry's Electronics, Sunnyvale, CA for $2.77 each)

A good quality, preferrably temperature controlled soldering iron, with a minature tip (tip should be narrow enough to avoid touching 2 I. C. pins at the same time). E. g. Weller type soldering station.

Good quality resin core solder (thin).

Approximately 4 foot of #24 AWG insulated wire and a good stripper for it and 2 feet of #22 AWG solid tinned copper bus wire. You will have to route 3 wires over a sequence if I.C. pins.

Desoldering wick and solder suction tool.

Philips type screwdriver (for opening your ST), tweezers, pliers, etc.

A steady hand and self-confidence.

Explaination of the modification :

(Please read the rest of this document before starting. It may save you time and an 520ST)

The current memory inside the 530ST consists of 16 256K*1 RAM chips. Address (A0..A8) lines are common to all those chips. The WriteEnable line is also common to all chips. Data (in and out) lines are of course individual. The RAS (row-address strobe) line is common to all chips. The 8 chis foring the high order byte group have one common CAS line, and the 8 forming the low order byte group have one common CAS line (CAS is used as enable for write operations, such that WriteEnable can be common to both groups). The high order group from MSB to LSB consists of U45, 44, 43, 42, 38, 34, 33, 32. The low order group of U30, 29, 28, 25, 24, 28, 27, 26. Note that all chips are adjacent, though the numbering has gaps. RAS0, CAS0H, and CAS0L are supplied from U1 pin 8,6 and 7 respectively (The 0 indicates bank 0)

Bank 1 that you are going to build in will be "piggy-backed" on top of the current chips, where all pins of the new chips EXCEPT RAS (pin 4) and CAS (pin 15) are soldered to the old chips equivalent pins. Thus they will end up sharing addresses, data, WriteEnable and power and ground with the existing chips.

All RAS pis of the new chips are wired together and will be supplied with the "RAS1" signal generated on pin 18 of U15 (the memory controller, marked 3H-2119C or so). The CAS pins of the 8 new high order byte chips (on top of U45..U32) are wired together and supplied from the "CAS1H" signal generated on pin 22 of U15. Analogously, the CAS pins of the new U30 to U16 are wired together and supplied with "CAS1L" from pin 21 of U15.

How to go about it:

Step 1: Open up your 520ST, pull off the keyboard connector and remove the main circuit card from its top and bottom shielding. Make sure to remember which screws go where and note the keyboard connector orientation.

Step 2: Desolder all of the capacitors adjacent to the existing RAM chips. (DO NOT SKIP THIS STEP. You'll lose time if you do, and worse, the modification will no be reliable

since you can't solder pins obstructed by the capacitors reliably (if at all)). To desolder them, I found it easiest to heat the island on the non component side, and bend the wires straight. After doing that or each capacitor, turn over to the component side and heat the islands wile pulling the capacitor out with the tweezers.

Step 3: Open up the holes of all the desoldered capacitors, using a combiation of de-soldering wick and suction tool. Do this from the non component side. If certain holes are difficult to open up, you may want to use a wood splinter. (push it through while heating). Be carefull to remove all solder debris!! THE REASON for opening the holes NOW is that they will be less accessible once you've done the other steps! Patience is a virtue.

(NOTE: Step 2 & 3 are the only ones that may damage your ST PC board. Be sure not to use excessive force while pullling out the capacitors. If you damage your PC board anyway, cure the problem now and not later).

Step 4: In this step we will piggyback the new RAM's on top of the old oes. Be sure to connect all pins except pin 4 (RAS) and 15 (CAS). The best way to go about this is to do chip by chip. First, bend the pins of the new RAM's suchthat hey are perpendicular to the package (instead of having slightly spread "cowboy legs"). Use pliers to bend pin 4 and 15 such that the legs are 180 degrees from their normal position, so they stick up in the air above the plane of the top surface of the chips. Don't make an absolute sharp 180 degree bend since some manufacturers' pins may snap off. Leave a little curve in the leg, but insure that is above the plane of the top surface of the chip.

Using #22 AWG to #16 AWG tinned solid copper wire you will form three buses along the top surface of the new d-rams. Cut a #22 AWG solid copper wire the length of the 16 d-rams on the PCB. The RAS bus is formed by soldering all the pin 4's of the new d-rams to the solid copper wire. The bus wire must be seated against the top surface of the new d-rams without a gap. This insures clearance between the top shield and the pins of the d-rams.

After soldering all 16 d-rams to the bus clip off any portion of the pins that extend above the top of the bus wire. Now cut a #22 AWG solid copper wire the length of the 16 d-rams. Place the bus wire along the top surface of the new d-rams in contact with all the pin 15's of the new d-rams. Solder every pin 15 to this bus and as above insure that the wire is seated solidly against the top surface of the new d-rams. Cut off all excess pin length sticking up above the top of the bus wire. Using diagonal cutters remove the section of the bus connecting the new U30 pin 15 to the

new U32 pin 15. This divides the bus in half with the new U16, 17, 18, 24, 28, 29 having a common pin 15. The new U32, 33, 34, 38, 42, 43, 44, 45 now have a common pin 15, seperated from the other common bus.

(NOTE: until step 6 is finished, do no in any way apply power to your ST. This intermediate state of affairs will damage your memory chips!!)

Step 5: Remount all the desoldered capacitors. Bend the pins like they were before resoldering, suchthat they will not touch the lower shielding. Solder from the non component side.

Step 6: Orient the 520ST PCB so that you are looking at the solder side of the PCB (non-component side), with the row of d-rams nearest you. Find the double square pattern of pads at the 68-pin socket of the memory controller, U15 (3H2119). The following is a guide to locating the six memory controller pins necessary to complete the wiring. The socket is numbered conterclockwise, starting with pin 1, the square pad (look closely) in the middle of the bottom outside row. The sequence, moving counterclockwise from pin 1, first on the outside square ONLY: (NOTE: the sequence ")(" means to make a 90-degree turn counterclockwise, i.e. around the corner)

1,3,5,7,9)(10,12,14,16,18,20,22,24,26)(27,29,31,33,35,37,39,41,43)(44,46,48,50,52,54,56,58,60)(61,63,65,67

The sequence, moving counterclockwise along the inside square only, and starting with the left side of the bottom row:

(62,64,66,68,2,4,6,8)(11,13,15,17,19,21,23,25)(28,30,32,34,36,38,40,42)(45,47,49,51,53,55,57,59)

Six 68-ohm 1/4W plus/minus 10% carbon film resistors must be added when adding memory. These series terminating resistors minimize undershoot which may damage BOTH BANKS of d-rams if omitted. Solder a 68-ohm resistor to pin 18 of U15, RAS1. Solder a #24 AWG stranded wire from the remaining end of the 68-ohm resistor to the pin 4 bus (RAS) of all the new d-rams. that is the new U16, 17, 18, 24, 25, 28, 29, 30, 32, 33, 34, 38, 42, 43, 44, and 45.

Solder a 68-ohm resistor to pin 22 of U15, CASH1. Solder a #24 AWG stranded wire from the remaining end of the 68-ohm resistor to pin 15 bus (CAS) of the new U45,44,43,42,38,34,33,32.

Solder a 68-ohm resistor to pin 21 of U15, CASIL. Solder a #24 AWG stranded wire from the remaining end of the 68-ohm

resistor to pin 15 bus (CAS) of the new U30, 29,28,25,24,18,17,16.

For best results in all three cases above solder the wires coming from the resistors to the middle of the three bus wires in a "T" fashion rather than at one end of the buses.

Use a continuity tester to find the following three traces -- do not depend on visual inspection. Now install three 68-ohm series terminating resistors in the original 512K bank of ram. Be very careful while soldering to these narrow traces, since excessive heat can easily lift a trace from the board. Use an Exacto knife to gently remove solder mask from traces.

Cut the trace leading from pin 8, RAS0, of U15 near U15. Solder a 68-ohm resistor in series with the trace.

Cut the trace leading from pin 6, CAS0H, of U15 near U15. Solder a 68-ohm resistor in series with the trace.

Cut the trace leading from pin 7, CAS0L, of U15 near U15. Solder a 68-ohm resistor in series with the trace.

Step 7: Sit back. Use Brain. Do you feel confident about the quality of your work? No mistakes? Check evrything once again if you are but a little uncertain. Applying power with errors might make your ST into a decorative, nonfunctional piece of art. OK. Either rebuild your ST into its shielding and cabinet, or put it onto a surface clear of wires and solder remians and connect it to monitor, disk and supply. Boot it.

It it boots, you're probably there. Test if the new memory works by looking at the phystop variable ($42E) with SID if you have the developer stuff. It should read $100000 (1M hex). Also note that memcntlr ($424) now holds 5 instead of 4, and that v_bas_ad ($44E) now holds $F80000 (screen bitmap origin). If you don't have the developer stuff, try a single drive copy and check that you get the whole disk in one buffer instead of two.

If the new memory does not seem to exist, use SID to deposit and retrieve words on locations $80000 and up (1/2 Meg hex). If bit errors occur, the ST bootROM did not detect the extension (it checks all bits of 512 locations by testing a psedo random sequence, before accepting a memory bank). Try to pin point the faulty chip(s) and remove the error.

If it doesn't boot, you're in trouble. I'm sorry. It is difficult to give hints on what to do here. So many possibilities. Desoldering the new chips probably won't work (if the old ones were functional, the ST would still boot).

Check for hidden short:circuit on the RAM pins. May also be
that you have a flaky new pin connection.

That's all there is...

     The new 520ST will be similar to the original machine, but will
sell without a monitor for less than $300, Katz said. The original model
sells for $799. Unlike the first machine, users will be able to connect
the new 520ST to their televisions.

...The new 520ST will be distributed through
mass merchandisers, such as K Mart and through regional discounters, said
Atari Executive Vice President Michael Katz.

Does anyone know when and where this machine is going to be available?

Not to worry - this is the result of a bug in the memory management routines
in the current TOS. I understand the problem has been fixed in the ROM
version of TOS. This is one of several reasons I want to get my hands on
those ROMs ASAP!!!

What is it about dropping the price on a machine (which can do more than
computers selling for many thousands of $ a few years ago) changes it to
a toy?

A while back, a couple of people posted articles about an implementation
of MODULA-2 for the ST from a company in England. Did anyone actually
receive it? How complete is it in respect to Wirth's MODULA-2 book, rev. 3?
How do you like the environment it gives to the user? Is the documentation
complete and accurate?

Thanks in advance for the info. I have been looking for a good implementation
of MODULA-2. I'll definitely get this package if the responses are positive.

  Hooray! I bought a C64 at Toys'r'Us a couple of years ago, and now I
  will probably by an ST520 there. Soon there will we millions of ST's
  in use with reams of software at reasonable prices. No more supporting
  some flaky, overagressive, undereducated speciality salesperson.

  Thanks, Jack Tramiel, you HAVE done it again!

  Bye, bye Amiga (with a tinge of regret).

Folks -

     I am getting rather tired of explaining this over and over again, when the Internet protocols are available for all to read (RFC's 821 and 822).

     Please rest assured that I know what I am talking about. I was a member of the committees that designed the Internet mail protocols, and have been the developer of the mail system used on SU-SCORE (and other TOPS-20's) for years.

     There is no such thing as "Errors-To" in the Internet protocols. It is a fantasy invented by certain Unix-based mailers to compensate for deficiencies in Unix software and protocols. You can be quite confident that "Errors-To" was generated by some Unix system.

     The TOPS-20 mail system uses upper case for things such as host names. In general, if you see something that has a lower case host name you can be confident that it came from some Unix system.

     The purpose of "Return-Path" is ***** NOT ***** to be the "true sender of the message" which Mabry Tyson erroneously states. The "Return-Path" is the path by which errors in delivering the message should take.

     In other words, for once, the Unix mailers which are generating return paths (which are not really in the header; they are outside in the "envelope") are doing something quite correct and reasonable. By setting the return path to be INFO-ATARI-REQUEST@SU-SCORE.ARPA they are stating that delivery error notifications should be sent to the maintainer of the INFO-ATARI list.

KMart (or whoever) can hardly be charged with undercutting
the computer stores by selling unbundled 520STs for $350-$400.
Last month after I first saw an ST, I mentally calculated the
price of the bare computer as follows:

```
System Price  $800 $1000 (color)
- Monitors    $150 $350 (reasonable guesstimates)
SUBTOTAL  $650 $650 (Same either way)
- Disk (SS)   $250     (price quoted for 2nd drive)
SUBTOTAL  $400     (for BARE machine w/ Mouse)
- Mouse       $ 50     (guesstimate)
BARE CPU  $350
```

So, $400 for CPU plus mouse is just "list" price.
$350 for them would be good buy but not "undercutting."
Of course, mail-order already has $100 off the system price.

I like to look at things in computer stores (quiet surroundings)
but would NEVER buy anything major there -- they all want
list prices (I remember $900 for an Atari 800 back in late '82)
and their salespeople, while better-mannered than at KMart,
are no more knowledgeable in some cases than at Radio Shack.

Trouble is, you can't hook any standard types of disk drives
or monitors to the ST (what military surplus depot sold them
all those Cannon connectors?! Talk about DELIBERATE
incompatibility! Try and buy one of those!).
Hopefully, the KMart version will allow not only a TV,
but standard mono and RGB monitors as well.

That raises another disturbing question: Can the KMart ST
also support the Atari monitors, especially the 70-Hz
non-interlaced mono job? Sure hope they put ALL these options
in the GEM desktop. In other words, I hope they don't rip
anything out of the current ST to go to KMart.
     mike k
PS: Look at the Jan/86 BYTE photo of the ST board.
See that big blank area in upper center?
Room for a TV RF modulator? Or a REAL power supply?

I wish people would stop saying that they "can't help thinking of
a $400 computer as a toy".... It's not the PRICE that makes a toy
computer, but the capabilities!
~~~~~~~~~~~~~~~~~~~~~~~~~~~

Anyway. A recent msg mentioned that the C-128 will give the re-located ST a stiff competitor, stating that it can run CP/M programs. If I remember right, there is a CP/M emulator for the ST (somewhere), similar to the PD-DOS emulator claimed for the Amiga. N'est pas?

It was recently asserted here that UNIX runs on the IBM PC without an
MMU. Well ... sort of.

The segment registers can be used as an MMU, if you keep programmers
from using them. Since that can't really be done on an 8086/88, PC/IX
(and VENIX, Xenix, ...) on IBM PCs doesn't really count as secure.
(Ergo it's not UNIX.) Processes can mangle each other at will.

In short, it's not really UNIX there, and it pretty much DOES have an
MMU. Better than nothing, but I wouldn't buy it. UNIX needs at LEAST
memory mapping. This can be real cheap! but the 520ST doesn't have it.

[Does this bug still exist?]

I'd be interested in finding out what different types of printers people are successfully using with their Atari 520STs. From the budget dot-matrix to the esoteric laser, any and all replies are sought. Please email your replies with the following format:

```
Manufacturer:          Model:
Retail Price: $             Price Paid: $
Where Purchased:
Type (letter/.matrix):
Print Speed:
Replacement Ribbon Prices: $
General Description: (e.g., 10" carriage, ink jet, friction only, 7 fonts)
Problems: (e.g., registration is OK with tractor feed; friction is the pits)
       (this thing is a boat anchor because it's too noisy and unreliable)
       (I should have bought model Z; the control codes are a disaster)
Caveats:  (this model is no longer in production/no longer available)
       (the manufacturer is no longer in business)
Comments: (this thing is the greatest thing since sliced bread because...)
```

Thanks in advance,
Phil Rastocny

There has been considerable recent discussion of the merits of ACTION!
To summarize, buy ACTION! if you have any real interest in programming
the Atari, otherwise stick with Atari Basic.

Mild Flame! Before I encountered ACTION! I was able to use a friend's
system who had the MAC/65 and C/65 conglomeration. I was appalled by

the list of C constructs not supported by C/65, e.g. "for statements, do-while statements, switch statement," and all of the more exotic C constructs. That was a bad start, but I found it to be quirky as well, e.g. keywords had to be in UPPER CASE to be recognized. Finally, the bother of shifting between editors, compiler, assembler to get an executable was a real pain (this is one of the *main advantages* of ACTION! -- it is easy to do this with ACTION!).

I encourage you to learn C, but I have yet to find a C in the Atari 800 world where you will learn anything very useful except frustration tolerance.

>take a 520 st, put it in a dark closet and leave it alone. when it grows
>up it'll be an amiga).

So which is it? Leave_them_alone or sling_more_silly_insults? Make up
your mind!!! Maybe the above quote should be re-stated:

     take an _amiga peecee_ owner, put them in a dark closet. when (if)
     they grow up they'll be more consistent in their arguments.

I will agree that it is a waste of time to continue this debate over
the two respective nets. Why don't we move the discussion to
net.silly.insults where it belongs?

>Atari has not to my knowledge offered to sell the monitors other than
>as part of a package deal. (I personally tend to favor the monochrome
>version - it seems to be best for the things the ST does the best.)

This is simply not true. A color monitor may be added to the
monochrome system for less than $300. Alternatively, a monochrome
monitor may be added to the color system for less than $200.

>2) I expect a computer to be good for handling text, but for a
>*personal* computer, I also enjoy sound and graphics capabilities. If
>Atari users were all the sensible sort who want only the minimal
>graphics required for text, one would expect only monochrome STs to

>(admittedly a small sample) claims they are going about 50-50. Perhaps
>even some sensible Atari users enjoy graphics.
>   With the ST, there is a choice between optimized color graphics
>and optimized text that must be made at purchase time.

Although the monochrome monitor is optimal for text processing, the
color monitor is more than adequate for the job (I own both).

>4) Commodore/Amiga has been fairly open and honest about the internal
>structure and functioning of their machine, while by comparison
>Atari has been relatively secretive (specific examples furnished upon
>request).

On the contrary, Atari is willing to furnish development kits to anyone
willing to spend $300. Until recently, Commodore/Amiga refused to sell
their development kits to anyone other than "official" developers.

>5) I have not heard much about ST expandability in terms of processors,
>more memory, etc. The Amiga was designed with such expandability in
>mind,and has bus ports, etc. for that purpose.

This, for me at least, is the ST's biggest shortcoming. Although
expansion boxes are currently under development, the designers of the
ST should be chastised for this serious omission :-(

>6) Most of the Dhrystone benchmarks run on the Amiga (showing slightly
>slower execution than the ST) have been run with the processor using
>the same memory as the specialized chips. With an expanded memory
>space (which could be desired for its own sake) performance should be
>enhanced, especially for graphics-intensive applications. A faster

>What should really give floating point performance a boost is the
>addition of a good floating point processor chip (of which the 68881
>is a logical choice for the 68000 family). I expect a 68881 to be
>available for the Amiga long before the ST gets one (if ever).

I would say that ~500(?) v.s. 1092 Dhrystones is somewhat more
than "slightly slower". Also, I thought the Amiga was not bogged down
by the specialized chips. Needless to say, both the Amiga and the ST
would execute the Dhrystone benchmark test faster with 68020's. And
what makes you think (seriously) that the Amiga will have a 68881
before the ST?

>7) A minimal Amiga system I would buy (512K, RGB monitor) costs
>considerably more than a minimal Atari 520ST system I would buy.
>I think the Amiga would better suit my intended applications.

There is no doubt about the fact that the ST is less expensive than the
Amiga. If the Amiga suits your needs better, then buy an Amiga.

>8) Jack Tramiel of Atari has announced an intention (as of a few
>months ago) to eventually sell hard disk and CD drives for ~$500.
>Even if this figure cannot be met, Atari may still come out with
>peripherals at much lower prices than those Tecmar is expected to
>charge for peripherals for the Amiga. Following this observed
>disparity, prices may be driven to more reasonable levels, to the
>benefit of the consumer. In general, competition between the two
>machines may help to keep prices in check.

Randy Magruder,

I suggest you pickup an ANTIC magazine and in their catalog section look
at a program called Chameleon. It's a modem program that emulates a vt52
and can handle xmodem and kermit file transfers. I believe it costs about
$19 from them and I've seen it for about $12 in the stores. They also
sell ($10) just kermit but I don't know if you need Action! to use it or
not.

By the way, Action! is a terrific language for the 800 series, and the price
has gotten VERY reasonable (less than $50).

>Can anyone discuss the relative merits or otherwise of OSS's ACTION! cartridge
>vs. their C/65 compiler.

I have both and wish I could give a detailed comparison, but, in truth I haven't used the C compiler much at all (this is by choice, not chance). On the other hand I have used the ACTION! compiler extensively. The way I see it, if you want portability then use the C compiler. If you want the most powerful high level language available for the Atari then use ACTION!. What makes ACTION! so powerful is that it was designed specifcally for the Atari, so it provides better access to the Atari's special features. Another big plus is that ACTION provides such a nice programming environment. It's integrated editor and compiler and it's fast compile times make it a joy to use. With C/65 you must ...

1. load an editor
2. edit and save your program
3. load C/65 and compile your program
4. load Mac/65 and assemble your program
5. run your program

With ACTION! (with small programs)

1. edit program
2. compile (less than 5 sec.)
3. run

With big ACTION! programs the source code must be saved to disk and compiled from there. This is still much faster than C/65.

On the other hand ACTION! is only available for the Atari so for portability it is as bad as you can get. However, I have been told that Clinton Parker is working on a version of ACTION! for the Atari ST.

I hope this helps and I hope that someone who has used C/65 more extensively can give it's good points (such a person will be harder to find because ACTION! out sells C/65 100:1).

JOHN

I have used C/65. My big problem w/ it is that it does not compile
into binary, but it produces MAC/65 assembly code. It is nice to have
this OPTION, but not to be forced into it. DISK SPACE GOES FAST!.
Forget about the extra time to assemble it! Unless you have a hard
disk it does not seem worth it.

Deep Blue C (from APX) produces a small intermediate code file (similar
to the p-code used by UCSD Pascal systems...but it is a c-code I guess)
that needs to be run with an interpreter package. It is not as bad
as it sounds, but Action! is definately faster.

So long for now,
              -Richard Hartman

Keywords: cheap, 1040ST, dealers, discount houses
Summary: New Chain Store ST Machine <$300.

Excerpts from article by Ken Siegmann, Times Tribune Staff:

Atari Corp. Chairman Jack Tramiel is trying a strategy that infuriated computer retailers once before. Atari will on Jan. 15 roll out a cheaper version of its 520ST computer...The new 520ST will be distributed through mass merchandisers, such as K Mart and through regional discounters, said Atari Executive Vice President Michael Katz.

While chair of Commodore International Ltd. in the early 1980's, Tramiel won infamy among specialty computer dealers when he sold the C64 through mass merchandisers at a price less than it had cost dealers.

The new 520ST is one of two new machines Atari plans to ship this month. The other more sophisticated machine -- called 1040ST -- will go exclusively through computer specialty stores, Katz said. He thinks it should keep them happy because it will keep them "on the cutting edge of Aatari's technology."

The new 520ST will be similar to the original machine, but will sell without a monitor for less than $300, Katz said. The original model sells for $799. Unlike the first machine, users will be able to connect the new 520ST to their televisions.

The 1040ST will have twice the internal memory of the 520ST. It will store up to 1 million characters of information, or 500 typewritten pages. With a b/w monitor, Atari has priced the machine at $999. With a color monitor the 1040ST will sell for about $1200.

The article quoted several analysts as saying the dealers are gonna be upset. I guess the 1040ST will be out in time for people to do their taxes on it (sorry :-))!

For those of you who read the article in net.micro.atari about upgrading to
1meg of memory on the ST, DON'T!!!! First of all, the references to the
different gauge tinned bus wires and non-tinned bus wires are not clear as
are the directions for adding the resisters to pins 6, 7 and 8 of the memory
controller. Second of all, when you finally get all the wiring done and turn
on the computer, the screen comes on for about 2 seconds and then goes blank
without booting the drive. Trying to reboot again does the same thing. I
suggest to all of you to wait for some kind of commercial memory upgrade
before you fool with your ST. If anyone can tell me what chips I fried from
my description, I'd appreciate it. I hope they were just the memory chips. (I
tried the two TOS chips, the drive controller, and the graphics chip in another
520ST and they work fine, so that just leaves the MMU, GLUE, and the memory
chips.

I guess I was a lucky one. I've upgraded to 1Meg and everything worked
right the first time. I have to disagree about the clarity of Gert's
instructions. I found them very easy to follow, providing step-by-step
guidance through the procedure. My guess is that you fried a DRAM (they're
very intolerant of static electricity... Did you ground yourself to a
local ground every time you handled them?

Well, Tramiel has done it again. It was just announced that the 520ST will sell without a monitor in toy stores for less than $300. The computer specialty stores are *furious*, many "I told you so"'s are floating around. It's just what he did with the C64 when he was at Commodore. I wouldn't be at all surprised if the computer stores dump the ST en masse, even with Tramiel's promised 1040ST for them only (we know how much THAT promise is worth).

I'm glad I didn't waste my money on an ST the way I did on the 8 bit series (400,800,1200XL). I saw what once were serious graphics engines (that happened to play neat games too) become toys only, and it's happening all over again.

Bye Bye Atari Pie

Bye, Bye, Atari Pie
Tramiel did it with the C64 and now with the 520ST
It'll sell at toy stores for less than $100 times 3
So much for stores where computers are the speciality
So much for stores where computers are the speciality

Have you heard about deja vu?
Do you have faith in Tramiel too,
Just cause his salesmen tell you so?
Now do you believe that it'll continue to sell
When the computer stores tell Atari to "Go to Hell"
And can you see Amiga sales really grow?

Well I know you love your 520ST
Cause I saw you hacking on it 'till 3
You all felt it was great news
Now what'll you do about the Tramiel bad marketing blues?

...etc...

The fact that your screen has raster for two seconds and then goes blank
does not mean that you fried anything. My guess is that all chips are
fine. Look for solder bridges (your new connections) in the following
way: hold the board up to a strong light (light is on the underside of the
board and you are looking from topside of board) and USING A 10X MAGNIFYING
GLASS (important - use a GOOD magnifying glass) scan all new connections
visible from topside for bridges. Then, turn the board over and inspect
all new capacitor connections. If you bent the capacitor leads too much
one or more may be making contact with some trace. Then, reseat the
memory controller chip. Sometimes board flexing will unseat that chip.
I suggest you do all this work on a table covered with sheets of aluminum
foil and make sure you, the board and anything that contacts the board are
at the same electrical potential by keeping everthing in contact with the
foil (with the power off, of course) as often as possible. When you power
up make sure the aluminum foil is somewhere else. This message is being
brought to you by a fully functioning 1MEG 520ST.

P.S. If the above fails I will buy the board from you (with everything
on it) for, say $50.

Summary: I'm getting tired of this.

I'm *really* getting tired of this discussion. I have answer Mr. Kenyon privately via 'mail' but this posting shows that it is likely he has not been receiving my mail. As such, I hope the Atari fans will bear with me and we'll all hope he reads this:

In article <933@mcvax.UUCP> simon@mcvax.UUCP (Simon Kenyon) writes:
>
>what about all the relocation fancy footwork that unix does
>to handle the per process data area

OS-9 does the same or similar 'fancy footwork' without an MMU

>what about multiple processes

OS-9 handles multiple processes without an MMU

>are we proposing going back to the dark ages of rsx (unmapped)
>where programs were linked for different load addresses

No. If OS-9 can do it, then you can do it with some other Unix or Unix clone. Then again, why bother, you'll have OS-9 anyway. :-)

>memory mangement is required for two reasons
>protection and reloxcation
>the first you can live without (that is if you never have pointers
>which point nowhere)
>the second is kind of hard to live without

I can live without the protection. I *have* been living without it on my Color Computer, running OS-9 (6809) for some time now. I think most Atari 520ST users will find it quite satisfactory. Please go look at OS-9 68K before you do any further posting. I read net.micro.atari to read about Atari.

Lines: 35

Manufacturer: Epson   Model: DX 20
Retail Price: $ Don't Remember   Price Paid: $ 290
Where Purchased: Lyco (Mail Order)
Type (letter/.matrix): Daisy Wheel
Print Speed: 20 cps
Replacement Ribbon Prices: $ (uses standard epson ribbon cartridges)

General Description: Diablo 630 Compatible, Bidirectional Priniting,
Uses standard diablo print wheels, uses stamdard epson ribbon
cartridges, Character Pitches: 10 cpi pica 12 cpi elite 15 cpi
condensed Propotional Spacing (1/120 inch programmable),
Line Spacing: 1/6 inch or 1/48 inch programmable,
Paper: friction feed 7 o 13 inches, Pin Feed with optional tractor,
Universal Interface senses 8 bit parallel (centronics), or Rs232 or
Ieee 488 (GPIB). 1K buffer built in. Nice manual.
Works nicely with STWRITER. The printer configuration file was very
easy to make up because of the excellent documentation.

Problems: Slow (but what do you expect from a < $300 daisy wheel printer),
       on the noisy side (about the same as the diablo).
Caveats: Difficult to print 66 lines on a 11" sheet of paper as the
     paper out sensor goes off at about the 63'rd line. To get
     66, the top margin has to be reduced, resulting in a page
     that has too much space at the bottom.
Comments: This printer was purchased for writing letters, short memos

etc. In my opinion, this printer serves that purpose perfectly. The
print quality is excellent (at least as good as any other daisy wheel
that I have seen). The price i believe is the lowest of any daisy
wheel printer (except it brother the Dx-10) on the market.

I recently received the assembler program and docs. Unfortunately the docs
were not saved correctly and were consequently lost. Could someone please
mail me them again? Thanks in advance.
Preferrably one letter will suffice (the original author?).

Some very reliable sources tell me that there is going to be a 1024ST announced
this month. It will be $999 (monochrome) and have 1meg memory, and a built in
DSDD floppy. Also the $599 20 meg disk. Don't know about when they are
shipping...

Instead of flaming about whether or not Unix* can run without memory management, why not examine the actual problem. Bringing up whether or not OS-9 can run without an MMU is silly. That's like saying that since both wood and gasoline burn, you can put logs in your car's gas tank.

Most people consider Unix to comprise a full Unix environment including all the system services and multiprocess facilities provided by a Unix system. In other words, a shell and some package that emulates Unix system calls is *not* Unix. If you have multiple processes running in a non-memory managed system, you are restricted to one of the following:

. each process absolute-assembled into a different partition of memory (ala DEC RSX-11)
. only one process in memory at a time -- each process swapped out when it blocks or its quantum expires
. all software assembled to perform all memory references indexed by a base register, which is loaded by the operating system and which the program must not change (ala old IBM OS)

These are big problems. Remember, anybody can write software that does 90% of what Unix does without any of these problems. It's called CP/M or MS-DOS or DOS-II or GEM or TOS or OS/A+ or...ad nauseum. It's that last 10% that's difficult.

To be honest, I believe it is more economical to upgrade an ST to have an MMU than to do the required software hacking. What about the license cost? Gee, I'd think if you are going to fork over for a Unix license you might as well get a more competant engine to run it!

This isn't to say that some clever individual couldn't do something about "Unix for the ST". I'd suspect that what would be presented is a Unix-lookalike environment with some

shell and the Unix system calls, but not a real Unix. It's that
last 10% all over again...

In a recent article about whether or not the ST is good enough to UNIX,
a topic which is getting boring, Mark Crispin <MRC%PANDA@SUMEX-AIM.ARPA>
concludes his posting with an appropriate post scriptum (?):

> * Unix (TM) is a trademark of Bell Labs to describe the
> absolutely terrible operating system they have conned large
> segments of the computer industry to adopt simply because there
> is no other portable operating system with the necessary
> facilities. It also describes the philsophy of those individuals

> after 20 years of effort to make computers understandable.

But if they were not so mysterios, then consultants wouldn't be able
to get away with charging for ten hours what can be done in two. :-)

Not altogether true. If you process activator can handle relocation
information in an executable file, you can have multiple processes without
memory management. I see no reason why UNIX would not run.

Still, I agree with the opinion that it is much preferable to run with
an MMU for protection. It is cheaper to add an MMU than to spend alot
of development time getting around its ommision.

Rumor has it that the TT is the correction for this.

Someone was asking how to make their 520ST monochrome monitor
use the entire screen.

If you remove the monitor's cover (taking due note of the warning
messages plastered on the back and inside) you will find six

controls.

On the front left, are the vertical alignment, vertical height,
and vertical hold.

On the back right are the focus, horizontal center, and brightness.

To stretch the display, turn the vertical height control with a
cross-bladed screwdriver.

On my monitor, this gives a very nice full-screen display.
I found I had to slightly adjust the focus, and the vertical line
(width of a line at the top of the screen vs. the bottom) as well.

The one drawback I've noticed (I only did it two days ago) is that
graphics are stretched noticeably out of shape (eg circles look like
ellipses).

You probably got your wires on the bottom of u15 in the wrong places.
The instructions are a bit wrong in that the chip counts clockwise from the
bottom(wirng side). You probably haven't fried anything. You should,
however, install the other three 68 ohm resistors in series with
the RAS and CAS lines for the original memory chips. I just did 3
units this weekend and all work well. The symptom you describe can
be duplicated by moving the wires on u15. Also, if you don't put
the filter capacitors back in, the exact same symptom will occur, with
 NO damage if not left on for too long.

I recently purchased the Chamelian Terminal Emulator from Antic.
I like it, but for one problem. In half duplex mode (at least)

it appears to convert the ATASCII EOL character to CR only, with
no LF attached. This gives me trouble when communicating with
friends on Apple IIs and Macs (the Mac running the Hayes Smartcom
program). In full duplex, running on Compuserve or my local unix
machine, all is OK. Perhaps these systems append a LF in their
echo (I dunno).
I have the same problem with the same author's version of kermit
running in connect mode between my ST and my 800.

Has anyone out there had a similar problem? Better yet, does
anyone have an easy solution?

Please mail responses to me, I will summarize solution.

Thanks in advance,

What is the difference where the 520ST is sold? Just as long as the price is cheaper. Why should anyone want to supplement a 'computer store?' where half the time, the saleperson is just as ignorant about the machine as a typical K-Mart salesperson. What is the advantage of paying 300.00 more just because it is sold in a computer store?
And the machine doesn't magically turn into a toy just because it happens to be sold from K-Mart. If it is a good machine then it is a good machine, period. It is strange attitudes that hurt machines, not marketing. The public has been duped long enough with outrageously over-priced machines such as the likes of all Apple products.

ray (mass marketing is OK if you don't mind being out-programmed by a 10 year old kid who was able to afford to get one for his birthday.)

>   ...Mark Crispin

I know of one other alternative:

The binary file can contain a relocation list which identifies locations
that need to have a base address added when the program is loaded into
memory. When the program is loaded into memory, the load function ("exec"
in Unix terminology) relocates these addresses before the program is started.

This is exactly what TOS does. The relocation list is stored as a stream
of byte offsets to the next longword that has to be fixed up. There is
a reserved byte value that skips without relocating, so it is possible to
relocate any program with less than 25% file storage space overhead.
The maximum overhead would only occur if every single longword had to be
relocated. A typical C program requires much less overhead, below 5%.

It does take some time to do this, but not very much; the time is not
noticeable compared to the disk access time necessary for loading the
program.

It seems to work pretty well in TOS. Of course, one program can disable
another by writing to memory that it doesn't own, but that is a separate
issue.

Mitch

In reference to article from: ugjohna@BUFFALO.CSNET (John Arrasjid)

The instructions for the 1 meg upgrade seemed fine to me and my machine
worked just fine after installation. Sure is nice to have a 360K
RAMdisk and memory to spare for $42. I'm not sure this
task is for everyone, but if you've got the tools and skills, go for it!

I have successfully upgraded my 520ST to 1MEG using the original
instructions posted to the net. I have the following questions to ask:

1) has anyone successfully upgraded to 1MEG using the new,
   revised instructions?

2) has anyone who successfully upgraded using the old instructions
   gone back and successfully retro-fitted the resistors?

3) has anyone with the 1MEG upgrade installed ROMS (not EPROMS)
   successfully? (either with or without the extra resistors)

Thanks in advance for the info.

Take a look at the power supply (plug-in) box. It's a Novation.

>   I'm not sure if Atari still has any, but for the price, it would be
> worth finding out (if you need a modem, of course). There was an 3 page ad

I got mine at Sears on a huge Clearance table (lots of calculator, computer
and camera stuff) in a beat-up carton with numerous price stickers, starting
at $189, marked down through the ages to $6.00 (bright pink sticker).
At that price, I don't mind having a spare modem around, even if it is a bit
dumb.

I'm disappointed too. But the ST CAN do 640x400 mono!
What bugs me is that Atari can't just turn off two of the guns in
their color monitor and run it mono at 400 lines non-interlaced.

   First off, this is an Atari newsgroup, not exclusively an ST newsgroup.
You are more than welcome to abuse it (:-). Secondly, as a former new
8-bit owner, I strongly suggest purchasing the following: a memory map
book (e.g. Compute!s Mapping the Atari), De Re Atari (a technical manual),
and possibly Compute!s Third Book of Atari. The memory map will tell you all
kinds of good things about how to get the most out of your machine, and where
to go to do it; De Re Atari will explain what all the stuff in the memory map
book means; and the Compute compendium will have some nice examples of using
all this (I think it has an autorun example). I find the first two
indispensable.

>Also, I know that they'd LIKE Me to get the cartridge rather than have
>action! put onto a diskette, but is it possible to have someone put it
>on diskette for me? Would I still be able to run the stuff? and compile

>it?

   This is known as software piracy, and is generally considered bad netiquette to refer to openly on USENET. I would suggest buying the cartridge. I just did, and it's as nice as others have been saying. The time saved (over things like Deep Blue C) in the edit/compile cycle alone makes it worth the price. The only thing I really don't like is the cartridge dependency (though for a price one can get around that). (Oh, and the thing comes with the rapidly-becoming-standard license agreement wherein the cartridge could be an empty casing, and they wouldn't be responsible. However, it might be in bad taste to include this, so just forget I even mentioned it, OK?)

Not really. My suspicion is that most people that buy Amigas also buy a
monitor.

>The Amiga as it is shipped now really has 512K built in, 256K of user RAM
>and 256 of kickstart RAM.
Does the average user have access to that kickstart RAM?
A store i saw the Amiga displayed at couldn't run many of its demos because
the programs needed 512K. SOOO? WHAT gives ... what good is RAM you
can't access (just as Atari's TOS gobbles up ~206k currently)? The people
selling the machines INSIST you need a to buy 256k more to bring the machine
up to 512K. I think in a pragmatic way...they are right. The machine may
come with 512k but you can only use 256k. Please feel free to correct me
if i'm wrong but i think you are talking about vapor ram.

>The Atari has 512K of RAM of which 206K is used for the operating system.
>This leaves a little over 300K for user RAM.
>This is about comparable to (though
>slightly better than) a 256K Amiga.
ok. TOS/GEM (Atari's Operating system) is (as of the first of January) in
rom. So owners will be able to free up that 206k if they want...for instance
in my case it will cost me nothing. $0.00 . I don't know what will be
the typical cost if any. I imagine somewhere around $25

>The double sided double density floppy
>lists out at about $100 more than the single sided floppy. If you add this up
>you get $1099 for the Atari and $1795 for the Amiga.
>This makes the Amiga about 63% more expensive.
>This is much closer to 50% than it is to twice as much.

I would add $200 to get your machine up to 512k. $1995.00
I am still confused by your pricing...does this include a monitor. if
not you should really throw one in.
Is this all semantics. out of all this i am still left with the impression
i would be shelling out about twice as much money in order to buy an Amiga.

Has anyone had any luck with the xbios Xbtimer() trap. Every time I
try to use it I get 2 Mushrooms. I have tried my code in supervisor
mode and get the same result. Here is a short test program I wrote
to see what was going on. I use a control register value of 7 which
should give me a prescale value of 200, and data register value of 0
that should give me a count of 256 for timer 'a' on the 68901.
Theoretically i should get an interrupt frequency of 48 Hz.
(2.4576 Mhz / 256 / 200).

```
#include <osbind.h>
#define VOID int

long counter;

/* Interrupt handler */
VOID my_handler()
{
     counter++;
}

/* Start_timer */
VOID start_timer()
{
     VOID my_handler();

     /* Start the timer */
     counter = 0L;
```

```
     Xbtimer(0, 7, 0, my_handler);
}

/* Stop the timer */
VOID stop_timer()
{
     VOID my_handler();

     /* Stop the timer by clearing the timer a control register */
     Xbtimer(0, 0, 0, my_handler);

}

/* Stack pointer save area */
long ssp_save;

main()
{

     /* Save the super stack, get into super mode using USR stack */
     ssp_save = Super(0L);

     start_timer();
     while(counter == 0L)
          /* twiddle thumb */;

     /* Got interrupt */
     stop_timer();

     /* get out of supervisor mode */
     Super(ssp_save);

     Cconws("I made it!!\r\n");
     /* I never get the message */
}
```

Any help will be much appreciated.

Summary: Where do you get them?

Now that I've got my developer's kit (after less than 4 weeks over the Christmas break!) my mind is starting to turn to all that public domain C software out there. Only trouble is, I don't know where it is. Do I have to subscribe to Compuserve (and pay money!) to obtain such software?

It's seems odd to me that net.micro.amiga has so many C programs on it, while there is very little on net.micro.atari. Is this because of qualms of conscience on the part of ST programmers (<-- this is a term formerly used to describe "developers"), while Amiga programmers let their passions overtake them? Why is it that net.micro.atari consists almost entirely of hardware discussions and anti-Amiga rhetoric, while "they" spend most of their time talking about software? Does this indicate that ST discussion is going on elsewhere? If so, does anyone have a comprehensive list of the forums for ST software discussion and communication of public domain stuff? If so, I think this information should be posted for the benefit of those who would like to escape the soul searching of this newsgroup and get stuck into the programming side of things. Thanks in advance, ...ak.

Does anyone have any ideas for sending a "break" from the 520ST's vt52
emulator?

Has the ^C^C worked for anyone? - What BAUD rate were you using? I've
tried all bauds.
Right now I have to plug the RS-232 cable into a regular terminal, hit
the break key, unplug the cable from the terminal and plug it into the
ST, then type a return!!! (WHat a terminal emulator, all you need is
another terminal to make it work! {:-]}).

                        Thanks,
                        Geoff

Mark Crispin's message did indeed list all the practical or semi-practical ways
to implement Unix w/o an MMU. The people who responded to his message don't
seem to understand what the Unix fork() system call does; the Amiga TOS method
will not work in Unix. The fork() system call, remember, generates a new
process which is an EXACT COPY of the old process. Any pointers in the old
process's data are copied to the new process. But the semantics of fork()
require that those copied pointers now magically point to the COPY of the data
in the NEW PROCESS. Mark's message listed all the possible ways this could be
accomplished w/o MMU, save one, which is to somehow figure out which random
words of data in the data space are pointers and readjust them at fork time.
This is quite impractical, as anyone who knows something about C will realize.

As an aside, the Sage IV 68000 system had no MMU, and did run Unix. Or rather, it ran IDRIS, the Unix look-alike (which does have a Unix-style fork()). I don't know which of the methods Mark listed they used, but I suspect the first one: running only one process at a time in memory, and swapping it out before starting another one. At any rate, let the Sage IV be the existence proof that you CAN run Unix w/o an MMU, and let Mark's message be the explanation of how, and let's get on with topics more closely related to the 520 ST, which I don't believe will ever run Unix (though something else from Atari might).

Jack Tramiel would promise the moon if he thought he could get money for it.

I haven't heard anything about the "TT", but I do know a bit about the way Jack does business, so this "TT" promise might just be an attention-getter.

Look at his two biggest successes: the VIC-20 and the Commodore 64.

Neither are particularly amazing computers. The VIC-20 sold because it was offered so cheap that nobody could undercut the price (Jack T. tactic #1). Jack's marketing plan for the C64 was simply that he would offer "more bytes for the buck".

I don't think anybody's buying computers on that criterion anymore. Most consumers want to know: what can I do with it? How has the ST been doing?

Since the dma port is the only high-bandwidth port on the machine a detailed
description of it seems necessary. The rom port has no read write line so
it's useless for this and I think the moral to the MAC's "serial is all we
need" philosophy should be obvious by now. It all hinges on how general the
data that can be sent from the dma controller is. I sure hope that one can
use this port in a general purpose way and not just in disk-like protocol.
If I can't I probably won't buy one. Who knows how the port-dma controller
work? The information in the BYTE article gives no clues.

Does Jack Tramiel think he can get away with undercutting his competition, retailing his products at K-MART type outlets, and forcing the competition to drop their prices (and eventually drop out of business) again? The latest I have heard is that Tramiel has (for the second time now) got all of his distributors upset by lowering the price of the ST to about $400, and diverting his distribution to K-MART. Apparently AT&T will also sell the ST as a low end UNIX terminal.

I see a little bit of humor in this, as well as a bit of sadness. If software developers support GEM (and produce MAC quality stuff), then the Mac could very well disappear. After all, you can't beat the price for such comparable machines. The humor of it all is that Commodore Amiga was in a real awkward price position in the market, and now they stand alone as the mid-priced REAL Computer (I can't help but think of a $400 computer as anything but a TOY - albeit a great toy).

If Mr. Tramiel is trying to drive Commodore to its knees by forcing it to drop its Amiga price down near the ST's new price, he may be in for a rude awakening. What he has actually done is downgraded the 'a-priori' notion of the ST that we all have, and turned it into a real tough competitor for the COMMODORE 128. If the Amiga prices don't fall, then (MY OPINION) people might just give the machine the respect it deserves. There is a saying that goes "you get what you pay for", and to most people, the Amiga will still be worth the price.

At this point, I think we ought to stop the silly Amiga vs. ST debate and get on with one that is more worthwhile: ST vs. 128...

We all know about the ST, but the 128 is actually going to give it a run for its money (MY OPINION). On the software front, the 128 runs a few THOUSAND C64 programs, including the largest selection of graphics-arcade-etc. games. The 128 ALSO runs a few THOUSAND CP/M programs in 128 mode. The 128 is also packaged quite nicely, and is actually a

real "sexy" machine. To the mass market consumer, these things might outweigh other minor details like higher resolution, more horsepower, better (this is open to debate) peripherals, etc.

The Japanese tried to create a new standard a few years back called MSX. Although the MSX machines could never compete over here with the C64, I always felt that their reasoning was pretty sound. The buyer really doesn't care if he has a 1MHz 6502 or a 1GHz 68090 (I like inventing future chips) just as long as it runs the software they need to run - effectively.

I would also like to mention the possibility that Tramiel will end up selling thousands of UNIX terminals before he DROPS the ST altogether in favor of the TT, which is supposed to have a 32032 instead of a 68000 (I hope they still use GEM and 'C' so you ST owners will be able to move on up with ATARI products.

---------- don't flame me, I'm doused with gasoline ----------

This may or may not be what you want to hear, but it may be true, but is only my humble opinion (and therefore might not be).

/mykes

At $400, the ST might make a nice printer buffer for my Amiga....

I have 4 8-bit Atari's (a 48K 400, a 52K 400, a 160K 800, and a 64K 1200XL) sitting around mostly gathering dust (although I do use the 1200XL for printing my invoices). I've since gotten a somewhat more powerful home personal computer (a DEC 2020 running TOPS-20!), and I'd like to use one of the Atari's as a graphics front end. My idea is to connect one or more of my RS232 serial ports to the joystick ports and speak some flavor of ASCII commands (e.g. like REGIS on the late lamented DEC GIGI, but taking full advantage of what an Atari can do).

I'd probably use the 800 because it has a video output, so there'd be lots of memory for multiple frame buffers, etc. I'd prefer something that is either cartridge based or could be put in cartridge so it could run diskless. Reliability is important too.

Has anybody done anything like this?

Does anyone know how to produce programs which will print 40 column
text on the hi-res monitor? (using the C development kit)

How do you invoke the init function in Atari's Line A Interface in
C, especially in reference to obtaining the Font addresses.

It would have been nice if Atari could have answered these questions,
but according to Richard Frick, Atari has nobody who is an expert
at programming the ST (apparently only DRI does), and he was unable
to answer these questions.

Thanks in advance,
Ed Friedman

The new issue of AmigaWorld has an ad by Lattice that mentions the "Lattice
MacLibrary with more than sixty C functions for those who feel close to
the Mac". Has anybody tried this?

I have been looking for a while now for tools to develop code in C and assembler for a free standing 68000 board environment. Here is a summary on what I have found so far. Any additional information on any of these products would be appreciated. I need to be able to write interrupt and hardware drivers and incorporate them with C code to build up an environment. Also relevant is register usage (how many register ints and does the function call only push the ones used etc.) and compiler efficiency. I will summarize to the net.

Lattice - cross compiler from msdos to generic 68000. It sells for $1095 which include the Quelo Assembler. The literature they sent me doesn't say much about provisions for a free standing rom based target. I have heard good things about the Quelo Assembler and the literature they sent on it looked real good. But what about when I have to port 'printf()' and have to substitute my own character put and get routines which I've written in assembler? I'm sure they don't furnish source for printf and they don't mention how this is dealt with so I am leery. They do have a good reputation though. The price strikes me as steep.

Whitesmith - cross compiler from msdos to cpm68k or free standing. Sells for $1100. They sent me literature which describes pretty well how they deal with the issue of free standing romable code. Their compiler produces assembly and there is a separate assembler. This would make examining code efficiency and such very straightforward. They give the impression of being more familiar with this kind on development. Their standard library is built in such a way as to allow the programmers low level drivers to be linked in with it so the library is portable. Sounds like it would be better than the Lattice. Any comments? Stikes me as

expensive.

DRI - development package for the Atari ST. The price of $300 would allow me to buy an ST system and still not pay any more than for an msdos cross compiler! It includes a bunch of stuff (could someone send me a current list?) which includes assembler, linker, loader, a small shell with history and aliases and emacs - at least this is what I have been told. I have also heard that portions of TOS were developed in C with this package. If this is true it would mean that this is a trodden path which is very good. Someone commented that "the compiler is not so hot - but it works". I would appreciate any comments on what this might mean. In general I would like to hear a review of this package as it seems like the best deal to me. The Lattice compiler for the ST will be out soon for $150. Any comments on using this one for standalone code?

Have I missed any options? I have a ibmpc clone with a hard disk currently. I would like to think this subject is of general interest but replies to previous compiler inquiries would indicate that this is not the case. However, if anyone can be of any help please reply by mail and I will summarize to the net.

Thanks in advance.

The Amiga can't sample an input sound given the basic machine, however it has
the ability to playback sampled sounds once you figure how to get the
sampled data into the machine. Right now, I have to use a s-100 machine
that does know how to sample to do this. I expect it won't be too long before
it can be done directly with the Amiga once a simple ADC board is available
for it.

Offhand, I don't know about what kind of output filtering the Amiga has,
though it certainly sounds better than the raw 8-bit DAC output I'm using
with my s-100 system.

Ok all you 520st enthusiasts, its time to stop dreaming. The atari
st is an incredible low end home computer. But it is NOT an Amiga.

Sure, with some very difficult assembly language code (counting cycles!
egad!) - you can copy the bouncing ball, but if anyone seriously thinks
a ST can match up to the Amiga, they are crazy.

I don't own either machine, and probably never will, however I have
researched both. Both have merits of their own, but they are two
completely different machines. The Amiga is a better computer, flat
out, and it also costs twice as much. Which is better for the money?
I don't know, but I am tired of hearing atari salesmen, and atari
owners, blabbing that the ST is "the same thing as an Amiga". That
quote came directly from an atari salesman.

I am not about to list features, but if this letter makes you red, grab
the specs for both machines and see for yourself. No comparison.

The Amiga does not have any built in analog to digital converter
for digitizing sound. It only has digital to analog converters - two
to give stereo capability, each is 8 bit linear with a 4 bit (I think)
scaling volume control. There are proper anti aliasing filters which
cut off starting at around 7 kHz. Sound samples stored in memory can
be played through the D/As using DMA completely transparent to and

without slowing down the 68000. The Amigas bus operates at 14.4 MHz
half of which is used by the 68000 (i.e. at 7.2 MHz) and half by the
coprocessors which do DMA for video, disk I.O, sound etc. If things
get really busy then the video coproccessors can steal extra time
and slow down the 68K.

As far as I know digitizing sound must be done by an external device.

Hope this helps. Mike Gingell, ...decvax!mcnc!ecsvax!mjg

I had the same problem and called Richard Frick... It turns out that TOS
gives up all of memory to the application. (seems pretty stupid to me). So
in order to use Malloc, you have to first use Mfree to free up some memory.
Now what I haven't figured out is how to determine where to start the
Mfree????? It seems non-deterministic since depending on how many
desk-accessories are loaded, the application will be loaded at various
locations in memory...

Any ideas?

To the best of my knowledge, GKS was never intended to solve the
problems of windowing software. It is Device Independent Graphics
Application Utility. It supports output to multiple devices, in
multiple viewports and Graphic windows, but only from one process. It
never attempts to address overlapping windows belonging to different
processes. I suppose one could build a window manager on top of GKS
and treat different windows as different devices (workstations) and
using segments to restore obscured windows. But that is just using a
good program badly. It just doesn't apply.

ANSI X3H3 met in October to discuss the issues of display management
(such as window assignment and priority), color table arbitration
(which window controls the color table), and communication between

mouse, keyboard, and icons. "We won't be standardizing the user interface, but we'er looking to standardize ways the programmer tells the operating system what he wants to happen on the screen", Peter Bono. I haven't heard the results of this meeting.

Every window manager has different syntax for defining a window, moving it around, creating subordinate windows. Whether a window is updated implicity or explicitly after a change. Where the graphics information is stored that restores obscured windows (is it a BitBlt, or a display-list?). How the graphics information is defined is the job of GKS, or CGI. Both of those standards have features which are applicable to the window problem, but they are not intended to be solutions to it.

I have cross-posted this to net.graphics, I believe the discussion should continue there. I think it should be removed from net.lang.c.

There are three command line interfaces available right now for the ST
     - command.com : comes with the developers package. I have also
seen it on more than one bulletin board. Msdos like.
     - Micro C Shell : very nice includes history, history editing,
pipes, redirection, limited shell scripts, utilities like cc, pr, more
etc etc, from Beckemeyer Dev. Systems in Oakland, CA (for only 49.95).
The multitasking version is due in Jan. They are also putting out a
real time executive.
     - Hos : comes with Habba C. Again unix like, though not even
10% as nice as Micro C Shell.

BTW. your DBUG package is doing great on my ST.

*** REPLACE THIS LINE WITH YOUR MESSAGE ***
I just followed the instructions step by step and had no problem. I
have had this expansion in my ST for over three months, and have'nt
had any problem. The San Leandro Computer club is selling memory
expansion plug in boards (see this months S/T applications journal)
in case you don't feel like piggy backing the chips. There are also
some people who will perform the expansion for you for the cost of
parts, labor and postage, and guarantee it for 30 days. On of them i
seem to recall is the ST users group in florida.

I hit a lot of CTRL-C in rapid succession in the VT emulator. I don't
recall seeing an xbios call to generate a break.

It does have hardware to support graphics. The 68000 is certainly not
bogged down. The Nov. 85 Byte article comparing C compilers for the
Mac. had some benchmarks. The ST (using AClyon C compiler) ran these
benchmarks at 2 to 3 times the speed of the best figures published
there. The sizes were in the same league. So now you can make your
friend eat his words :-)

Tos itself does not have a command processor. There are three that i
have used.
     - Micro C Shell: extermely nice. Much like the one i am using
now.
     - command.prg : comes with the development system. Msdos
like.
     - Hos: comes with Habba C. Unix like, not quite as nice as
Micro C Shell.

> Can anyone recommend a C or Pascal compiler for the ST?
I use the Aclyon C compiler that comes with the Dev. system. I am
quite happy with it. I also have Habba C, that I would'nt recommend to
anyone.
I have'nt used any of the Pascals, but they are available from OSS and
Antic. How about Modula-2. It is available from TDI (Dallas) for
69.95. I am awaiting my copy. I have read two very favorable reviews.
Bsides I much rather have Modula than Pascal.

>
> Can anyone recommend a disk copying program (that handles protected
disks)?
Side Track from Monarch Dev. does a good job.
It only 24.95, and they also throw in a fast disk copy program.

>
> Can anyone recommend a RAM disk program?
>
I use M-Disk from Michtron. The new relese has the auto load feature.
The public domain one is not bad either. Using the source you can set
up your preferred size.

for the great line eater...

has anyone made any interfaces using the 130xe expansion buss?

I have made a simple parallel port off of it and I have a question.
do I need the 65XXA type chips (2Mhz) or with the 1Mhz versins work?

Keywords: atari 520st VIP professional review

NOTE: the following is a review of software for the 520ST.

INTRODUCTION: Yesterday I purchased the long awaited VIP professional integrated spreadsheet for my 520ST. I've used both multiplan and a Visicalc-clone writen by VIP technologies before. I use a spread sheet for home budgeting and analysis of my stock portfolio.

PRICE: $89.95

VENDOR: VIP Technologies

SOURCE: Von's Computer's, West Lafayette, IN

DESCRIPTION: The VIP professional is an integrated spreadsheet, database and graphics package, modeled closely after the popular Lotus 1-2-3. It comes with a 1/2 inch thick manual and a key-disk copy-protected disk. Also included is a "year" of telephone support (more on this later), an order form for adding longer support, an order form for an additional key-disk, a disk replacement order form, a GEM coupon (more on this later too), a registration card and a quick reference. The system boots off a backup copy but requires a look at the key-disk to start running.

My initial impression was extremely good. The program loaded easily and with a few glances at the quick reference I was building a spreadsheet and popping up a quick pie chart or two. After running a Visicalc-clone on an 8-bit machine (a Radio Shack color computer) this was heaven! Very fast, and very easy to use. Keep in mind that I'm experienced with using spread sheets, beginners might find this package a bit complex at first.

MINUS: First, the bad news. The VIP professional uses a lot of memory. So, much that it does not run with GEM-and-the-mouse as you may have seen in the demo. (I understand that is why it was delayed) The version you get now runs and looks like the IBM-PC version of Lotus 1-2-3. Text and cursor, no mouse. Also, to fit into the remaining memory, VIP removes GEM, forcing you to reboot via the reset switch when you leave the program. Crude. Finally, you are left with about 37k to biuld your spreadsheet in. For large two to three screen sheets that will not be enough (depends on what you do. My stuff *just* fits). Of course the copy-protection is not very nice either, but at least it's only a key-disk system.

PLUS: It is exactly like Lotus 1-2-3. I typed in a small sheet in a third party Lotus 1-2-3 book last night; worked exactly as written. I intend to try downloading some of the spread sheet templates from the CompuServe Lotus 1-2-3 sig. The VIP manual claims they should work if they were saved in "worksheet" mode instead of native mode. I tend to believe them, but we'll see after I try it.

Really nice manual; not good as a toturial (but you can use any of those Lotus ones (they list their favourites in the back of the manual)), but a good reference. You get a "year" of support which means 12 months or five solutions or 60 minutes of on the phone help. You can order more of that if you'd like (sorry I forgot the price for that). You can order additional key-disks, $15.00. You can order replacement disks, $20.00 (why the

difference? I dunno.) When you upgrade to 1 Meg memory or you get TOS in ROM, you can upgrade to the new version, $20.00. (I'm going to order an upgrade board after Christmas...) Finally, they'll write about upgrading to new releases. You also get a graph-enhancing program (let's you add special fonts for titles, etc).

COMMENTS: On the whole I'm very pleased with the package. Yes, it does have some serious problems, but after keying in my two and a half screen full budget, I find that the problems are not getting in my way. For a quarter of the price of Lotus this program is worth it, bugs and all.

Thanks to all who contributed information. A compendium of the full text of responses is available on request. Attached is a brief summary of the recommendations. My apologies to those uninterested in the info.

SpeedScript 3.0 Public Domain (free) package that is better than most commercial (expensive) ones. Distributed free with...

OMNIVIEW 80-column software modification by David Young.

Letter Perfect - LKJ Enterprises, St. Louis. A+ ratings except that it takes some effort to learn and uses a nonstandard DOS format on the disk, "a disadvantage" as Consumer Reports would say. Translation program, LP DOS to Atari DOS, available from vendor.

Action! Contains a very nice built-in editor and is itself a useful high-level language.

Paper Clip By Batteries Included. Has two-window capability. Mentioned favorably by several both on and off this net.

Bit-3 Hardware 80-col mod for Atari (someone confirm?) Does this give prettier results than the software ones?

Atariwriter Atari's own WP. OK but "very limited" e.g. 3-page limit.

Bank Street Writer - Broderbund Software, Inc. Good for beginners (easy to

learn) but cumbersome to use for heavy editing because
of menu format. Well-written manual, capabilities for
manually chaining files to page-number large documents etc.
Austin-Franklin 80-col conversion source mentioned by David Young;
no further information.
Letter Wizard Easy to use WP system, 40 col only, 3 pages maximum length!
Homeword Super-Text - aconversion of very good Apple system which
didn't retain all the good stuff from Apple implementation.
Wordman Merely mentioned by David Young.
MEDIT + FORMS Atari program editor and formatter. David Young says he
has used this as a Word Processor (powerful but slow).

I am beginning to conclude that one can indeed do serious word processing with an Atari 800XL. SpeedScript, Paper Clip and Letter Perfect all seem to be good choices, with various pros and cons. 80-column display capability seems likely to be useful to check formatting, but one might want to operate in 40-column mode (would you believe 38?) for ease of reading.

Thanks again for all the help.

As if I hadn't already caused enough trouble, my next question is what are the best printers to use for (a) Near Letter Quality and (b) no holds barred (except price) all-out camera ready Letter Quality printing? If high-quality graphics printing is desired, which ones emerge as best?

Also, is there (please dont laugh) a Fortran available for the 800XL? If not, is there another language suitable for semi-serious scientific calculations, if you don't mind waiting a little? Finally, are there any facilities for setting up a useable library of programs that will be linked automatically just because they are referenced in a calling

program? Thanks for any assistance that is available.

In article <617@ihlpm.UUCP> rtb@ihlpm.UUCP (Todd) writes:
> After reading a lot of articles about this years Comdex it is
>becoming more obvious that Atari has already won in the ST vs.
>Amiga wars.
technically

So Atari follows in IBM's footsteps, and succeeds with a technically
inferior product :-).

Seriously, I don't own either machine. I'm probably going to be buying one
in the near future (january), and haven't decided which. However, I want a
machine for twiddling LISP, which means (to me - I want to load the editor
and MasterScope and the online help and ...) lotsa-memory. Say, 4 Meg or so.
Atari doesn't seem to want to market a machine to do that. The Amiga is
open, and there are 2Meg boards on the market.

Of course, the plaintiff cries from people trying to twiddle the mouse from
C doesn't help the ST any.

And I'm going to ignore the prospects of Commodore going under. I'll pick

the machine that best does what I want, then support the company that makes it.

Final thought: I'd be suprised if the ST doesn't outsell the Amiga, by 2:1 or better. After all, I expect most people to look at them, see windows and two price tags (one roughly 1/2 the other), and buy the smaller price tag.

I hope Mr. Doyle didn't buy an Amiga JUST for digital sampling of sound.
Although the Amiga can play pre-recorded or synthesized sound samples it
does not have built-in user sampling.

The Amiga has a 6-pole (36 decibel per octave) low pass filter for each
stereo channel.

I am the resident sound software person at Commodore/Amiga and I'll be happy
to answer any questions about producing sound with the Amiga.

P.S. In case anyone is interested, ST BASIC does not take full advantage
of the new memory. I find I can now load large BASIC programs without
having to turn off GEM accessories and the Graphics Buffer but I still
cannot get the array sizes I want. In particular it seems that the maximum
amount of memory ST BASIC is able to devote to arrays is around 8192 (8K)
words minus some overhead (maybe 5 words) for each "column". For example
the following limits were found:

  1. DIM A(8187)
  2. DIM A(4093,1)   <<comment: there is a column "0" and a column "1">>
  3. DIM A(2728,2)

  4. DIM A(2045,3)
  5. DIM A(1636,4)
  6. DIM A(4091), B(4091)
  7. DIM A(2726), B(2726), C(2726)

I would greatly appreciate someone telling me how to get ST BASIC to allocate more space, if that is possible. Thanks.

P.P.S. Another peculiarity is that, by means of poke, one can find the highest byte address recognized by ST BASIC to be about 1014000 which is short of 1Meg by about 30000 bytes. Did I get gipped or what?

Oh, come off it!! Your message before this totally destroys
your credibility. You sell Amigas - therefore you are
biased in its favor. The ST is a great machine for the price;
the Amiga is a great machine, but I can't afford 1795 to get
one. Come down off your high horse and go use an ST - it is
a great machine, with a great price!!!

Thanks you all for all the information. What I gather
is the following:

1) Color is worse than b/w (for hacking)
1) Color isn't that bad, but...
1) Better get Color!
2) Single Sided disks are better ($),
   provided one gets a hardisk.
2) Double Sided disks are better for me.
3) Dealers carrying it are:
   -- Computerland on Hawthorne Blvd
      (160000 south or so)
   -- Lamar Microelectronics on Artesia Blvd
      (between Inglewood & Aviation) (213) 374-1673
   -- Personal Computers Etc. on Topanga Canyon
      in Woodland Hills
   -- CompuStart (on Wilshire, between 21-22 st).
      I got mine here. Cheaper than Lamar.
   -- Priority One Electronics in Chatsworth

      (but they try to cheat you)
4) Paul Lamar can do an upgrade to 1 Meg ($300).
   So can CompuStart ($200), and both void the warrantee.
5) The Citizen MSP-10 is a good choice for a printer.

The kit includes the following ($321):

 -- text editor (MicroEmacs)
 -- C compiler (a Digital Research, Inc. port of Alcyon C)
 -- assembler
 -- linker
 -- utilities
 -- Kermit
 -- Resource Construction Set
 -- It is well worth the money!

I got mine at CompuStart, and I paid around $2700 for a loaded
system (color, 1M, 2d2d, printer, dev kit, random software).
I'm not associated with CompuStart (blames to /dev/^1/tihs).

I really appreciated your messages. It really made me
change my mind about what I bought. Thanks a lot!

     Adolfo

Summary:

There are window standards being worked on by ANSI! At the last X3H3
meeting there was a small subgroup X3H3.win that spun of to start
specification of this standard. On of my Prof's here at U Lowell is
on this committe. I will try and get a brain-dump from him, and post
the status of this standard to the net.

I must agree with previous note, GKS and CGI are NOT window standards,
nor do they specifiy how to interface withh windows. CGI might be a
nice base for a window system/standard but GKS ugg to big, with to
many layers (in most cases) to add Wind managment on top of. I speak
after a summer of so a GKS implementation on top of a (pseudo)CGI.

U guys seem to have hit a problem I ran into some months ago.
Im my case I was using the developers kit. The patch involved setting up
a "truncate" call after the application program was entered, but before the
real "main" subroutine was called. "_end" marked the end of the data space for

the job.
If U are using the developers kit, then U have an out of date start-up routine.
Later distributions of the software (gems and/or gemstart.o) do the memory
deallocate for you at start-up.
Buzz me if U want more specific help.

I am not sure whether I can help, but I recommend the Manx Aztec compiler.
I am using the Aztec cross-compiler for the Apple-II and Comodore computers
on an AT&T 6300 (IBM-PC clone), and the system works very well. They also
offer a package for the 68K chip, but I don't know specifically whether they
offer a cross-compiler that runs on the PC and generates 68K code.

I am nothing but happy with their cross-compiler. I got the "commercial"
system on the PC, as well as the cross-compiler. The total package includes:
     - compiler for PC (3 memory models)
     - cross-compiler for 6502
     - assemblers for both machines
     - file transfer software (PC to/from Apple/Comodore)
     - library source for cross-compiler (useful!)
     - make, grep, diff, and `z' (like vi editor)
     - library archivers (2 of them)

I could not reach them by phone today to verify the 68k cross, because
their 800 telephone number is in New Jersey and so am I. As the little
mechanical woman in the telephone told me, they `cannot be reached from my
calling area'. They can be reached from outside NJ at 800-221-0440.

I have no affiliation with them what-so-ever, except as a happy user.

On financial woes:

It is true that Commodore posted a lose the last two quarters and is technically in default on some corporate bonds. However Commodore's stock, usually a good predictor of future performance is holding its value pretty well. Let us remember too that Atari is swimming in debt. If Atari does not have a very good Christmas indeed, it may disappear suddenly. Don't we remember all the cancelled 8-bit lines, the undelivered promises, the sweaty times at the start of this year, atari loyalists?

On software availability:

Lets see now. 520ST's became available in June and the software is now ready in December. Amiga's became available in September and the software is ready...in March? Well, some is available now, in December, which lets us all know where the relative priorities of software producers lie. I think it is easier to write programs for the Amiga and I think the designers think so too. I think good hardware design and good system software will beat early-to-market. I think no amount of partisanship by atari owners will keep the Amiga from becomming a success. I mean, look at the two newsgroups and you will see the future. .atari is full of articles doomsaying the amiga and .amiga is full of rich technical questions and hints. It is clear where the software brains are putting their efforts. Now, there are/were some bright people doing ST stuff too, and I think its place in the market is secure for awhile at least. But I don't tkink the Amiga is going away.

>> Ok all you 520st enthusiasts... The atari st is an incredible
>> low end home computer. But it is NOT an Amiga.

And thank providence for that! (thought I'd get a bit nasty, but Naah!)

>> Sure, with some very difficult assembly ... you can copy the bouncing ball,
>> but if anyone seriously thinks a ST can match up to the Amiga
>> they are crazy.

I am crazy.

>> I don't own either machine... however I have researched both.

I do own an ST, and also researched both.

>>Both have merits ..., but they are ...completely different machines.

Agreed.

>> The Amiga is a better computer, flat out,

Disagreed.

>> and it also costs twice as much. Which is better for the money?
>> I don't know,

You don't know? Don't know? Then WHY do you bother with this posting?
(then again, why do I waste readnewsers' and my time with responding?)

>> ... but I am tired of hearing atari salesmen, and atari
>> owners, blabbing that the ST is "the same thing as an Amiga".
>> That quote came directly from an atari salesman.

Salesmen's opinions rarely count, since they don't know
in most cases what they are selling (at least I never met a home computer
salesperson who did).
I never heard Atari owners say that the AMIGA is the same thing as an ST.
They know better.
>>
>> I am not about to list features, but if this letter makes you red, grab
>> the specs for both machines and see for yourself. No comparison.
>>
That's right, "NO COMPARISON". Why do people still get overwhelmed
with sound and light? Graphics chips may be give you ultra-super-dooper-whamo
BitBlt's 'n' things, but they will not compile your programs faster, nor
read your floppies any faster.

>   Oh, come off it!! Your message before this totally destroys
>   your credibility. You sell Amigas - therefore you are
>   biased in its favor.

~~~~~~~~~~~~~~~~~~~pop goes the ST~~~~~~~~~~~~~~~~~~~

i just fried my ST and after talking to atari and my local dealer i
have tracked down the problem. It is related to the 1 Meg upgrade
and the new proms, it seems that the early postings of "how to
upgrade ...." left out 4 critical resisters (60 ohm 10% tol); 2 must
be placed on the CAS lines and 2 on the RAS lines, all 4 go on the
MMU (i know it isnt really an MMU) side. the upgrade will work fine
w/o the resistors until you put in the new proms, the difference in
the current drain will cost you all your memory chips and possibly
the MMU.

Here are the rest of the ikbd commands, and a C program which will
read joystick 0 (sorry it took me so long to get back to this!).

Load Mouse Position

```
    0x0E
    0x00     ; filler (?)
```
~~~~~~~~~~~~~~~~~~~

```
     XMSB      ; X coordinate (scaled coordinate system)
     XLSB      ;
     YMSB      ; Y coordinate
     YLSB
```

Set Y=0 at Bottom

```
     0x0F
```

Set Y=0 at Top

```
     0x10
```

Resume - Resume sending data to host (after a pause)

```
     0x11
```

Disable Mouse - Disable mouse event reporting (any mouse command resumes)

```
     0x12
```

Pause - Stop sending data to the host

```
     0x13
```

Set Joystick Event Reporting (default)

```
     0x14
```

Set Joystick Interrogate Mode

```
     0x15
```

Interrogate Joystick

```
     0x16
```

Set Joystick Monitoring

```
     0x17      ;
     rate      ; time between samples in hundredths of a second

          Returns: (in packets of two as long as in mode)
               %000000xy
                      ||
                      |--- ; JOYSTICK1 Fire button
                      ---- ; JOYSTICK0 Fire button
               %nnnnmmmm
                ||||||||
                ||||------ ; JOYSTICK1 state
                ---------- ; JOYSTICK0 state
```

Set Fire Button Monitoring

```
     0x18
          Returns: (as long as in mode)
               %bbbbbbbb  ; state of JOYSTICK1 packed 8 bits
                       ; per byte
```

Set Joystick Keycode Mode

```
     0x19
     RX        ; horizontal velocity breakpoint (tenths of seconds)
     RY        ; vertical velocity breakpoint (tenths of seconds)
     TX        ; horizontal cursor key generation delay (tenths)
     TY        ; vertical cursor key generation delay (tenths)
     VX        ; horizontal cursor key generation repeat (tenths)
     VY        ; vertical cursor key generation repeat (tenths)
```

Disable Joysticks

```
     0x1A
```

Time-of-Day Clock Set

```
     0x1B
     YY        ; year (two least significant digits)
     MM        ; month
     DD        ; day
     hh        ; hour
     mm        ; minute
     ss        ; second

     NOTE: all time-of-day data should be sent as packed BCD.
```

Interrogate Time-of-Day Clock

```
     0x1C
          Returns:
               0xFC ; time-of-day event header
               YY   ; year
               MM   ; month
               DD   ; day
               hh   ; hour
               mm   ; minute
               ss   ; second

     NOTE: time-of-day data returned as packed BCD.
```

Memory Load - load ikbd controller memory

```
     0x20
     ADDRMSB       ; address of controller memory (high)
     ADDRLSB       ; address of controller memory (low)
     NUM       ; number of bytes (0-128)
     {data}
```

Memory Read - read ikbd controller memory

```
     0x21
     ADDRMSB       ; address of controller memory (high)
     ADDRLSB       ; address of controller memory (low)
          Returns:
               0xF6 ; status header
               0x20 ; memory access
               {data}    ; 6 data bytes starting at ADDR
```

Controller Execute - execute ikbd controller subroutine

```
     0x22
     ADDRMSB       ; address of subroutine in controller
     ADDRLSB       ; memory to be called
```

Status Inquiries

All status commands are formed by ORing 0x80 with the relevant SET command.
Valid Status Inquiry commands are:

```
     0x87 mouse button action
     0x88 mouse mode
     0x89
     0x8A
     0x8B mouse threshold
     0x8C mouse scale
     0x8F mouse vertical coordinates
     0x90 (returns 0x0F if Y=0 at bottom, 0x10 if Y=0 at top)
     0x92 mouse enable/disable (0x00=enabled, 0x12=disabled)
     0x94 joystick mode
     0x95
     0x99
     0x9A joystick enable/disable (0x00=enabled, 0x1A=disabled)

     NOTE: Status Inquiry commands are NOT VALID if the ikbd is in
           Joystick Monitoring Mode or Fire Button Monitoring Mode.
```

Phew! Now that you've got all that stuff memorized, you can forget most of it. As far as I can tell, the ST is set-up to not monitor the joysticks at all! If you use the Kbdvbase() call, you will get a pointer to a structure containing all of the ikbd handlers. Now, in the version of TOS I have, the joystick handler vector (joyvec) points to a RTS (return from subroutine) instruction. So, since I did not want to write my own handler, I used the simplest of the joystick monitoring modes, Joystick Keycode Mode, in the following program. If I eventually do write a handler, I will post it to the net also. In the meantime, enjoy!

```
/*
 * Atari 520ST Joystick/Keyboard Monitoring Demo
 *
 * Richard E. Sansom  December 1985
 *
 * This is a no-frills program which will monitor joystick 0, and will
 * report joystick events as keystrokes.  No claims are made as to its
 * efficiency (or elegance).
 *
 */

#include <stdio.h>
#include <osbinds.h>

/*
 * defines
 */

#define JOY_UP         0x48
#define JOY_LEFT   0x4B
#define JOY_RIGHT  0x4D
#define JOY_DOWN   0x50
#define JOY_FIRE   0x74

#define TRUE  1
#define FALSE 0

/*
 * globals
 */

static
char set_joy_key_mode [] = {

          0x19     /* Set Joystick Keycode Mode */
          0x00,0x00,    /* RX, RY */
          0x00,0x00,    /* TX, TY */
          0x01,0x01 /* VX, VY */

     };

static
char reset_ikbd [] = {

          0x80,0x01 /* Reset */

     };

/*
 * main program
 */

main() {
```

```
    int  lo_chr,hi_chr,more;
    long chr;

/*
 * clear screen, prompt for joystick
 */

    Cconout(0x1B); Cconout(0x45);
    printf("Plug joystick into port 0, hit any key when ready...");
    while (!Cconis())
         ;
    Cconin();
    printf("\n");

/*
 * write command string to ikbd
 */

    Ikbdws(6,set_joy_key_mode);

/*
 * loop until 'Q' is hit
 */

    more = TRUE;
    while (more) {
         while (Bconstat(2)) {
              chr = Bconin(2);
              lo_chr = chr & 0x00FF; /* ascii code */
              hi_chr = chr >> 0x10;  /* scan code  */
              switch (hi_chr) {
                   case JOY_UP: {
                        printf("Joystick UP ");
                        break;   /* Ok, so I'm no purist */
                   }
                   case JOY_LEFT: {
                        printf("Joystick LEFT ");
                        break;
                   }
                   case JOY_RIGHT: {
                        printf("Joystick RIGHT ");
                        break;
                   }
                   case JOY_DOWN: {
                        printf("Joystick DOWN ");
                        break;
                   }
                   case JOY_FIRE: {
                        printf("Joystick FIRE ");
                        break;
                   }
                   default: printf("Keystroke ");
```

```
            }
            printf("(scan=0x%x, ascii=0x%x\n)",hi_chr,lo_chr);
            more = !(lo_chr == 'Q');
        }
    }

/*
 * reset ikbd, exit
 */

    Ikbdws(1,reset_ikbd);
    _exit(0);
}
```

For those of you using the Hippo-C compiler - I've heard that not all
of the ST bios and xbios calls are defined (at least in the documentation),
so you may want to try the following defines, and see what happens.

```
#define Cconis() conis()
#define Cconin() conin()
#define Bconstat(dev) bios(1,dev)
#define Bconin(dev) bios(2,dev)
#define Ikbdws(cnt,ptr) xbios(25,cnt,ptr)
```

I don't know if you have a bios() call available, so you may have to
build your own:

```
    .text
    .global  _bios
_bios:   move.l   (sp)+,.save   ; save return address
    trap #13      ; call bios
    move.l   .save,-(sp)   ; restore return address
    rts           ; return

    .bss
.save    .ds.l             ; storage area
```

You may have to build your own xbios() call also:

```
    .text
    .global  _xbios
_xbios:  move.l   (sp)+,.save   ; save return address
    trap #14      ; call xbios
    move.l   .save,-(sp)   ; restore return address
    rts           ; return

    .bss
.save    .ds.l             ; storage area
```

I don't know whether the Hippo-C compiler pushes all of its args
on the stack as longs (the DRI compiler does NOT), so you may have to

take that into consideration also.

>short of 1Meg by about 30000 bytes. Did I get gipped or what?

No, you did not get gipped. The highest 32K of the 520ST is used for
the screen display. The end of the Transient Program Area (TPA) is
32K from the end of memory. Apparently the BASIC interpreter doesn't
allow you to poke past that.

|but if anyone seriously thinks a ST can match up to the Amiga, they are crazy
|
|I am not about to list features, but if this letter makes you red, grab
|the specs for both machines and see for yourself. No comparison.

It would be much more helpful if you stated WHY you believe that the
AMIGA is better than the ST. Since I may buy a new computer soon, I
would like to hear real information about the two machines. So far, the
main differences appear to be:

(a) the ST is half the price of the AMIGA.
(b) the AMIGA has better special-purpose graphics capabilities than the
    ST, but at the expense of main CPU speed.
(c) the AMIGA graphics is said to be not usable at a
    resolution of 640x400 for text or serious graphics applications.
(d) the AMIGA is said to be more expandable than the ST.
(e) the AMIGA has a multitasking operating system. Definitely a big plus,
    but as soon as OS9 is available for either machine, this does not
    matter anymore.

Since I want a 'workstation' that I can use as a terminal, for small
programming projects, and for word processing, points a-c seem to speak
in favour of the ST. I would like to hear how much truth there is to
these statements, and what other aspects of these computers limit their
usability for 'serious' work. And please refrain from uninformative
postings like the one quoted above that simply state 'the XYZ computer
is obviously superior'.
                              Thomas.

There is certainly more software advertized for the Amiga in the L.A.
area. It doesn't matter if the ST has more software at shows, if it
isn't being sold! There are also more places advertizing themselves
as Amiga dealers in the L.A. area.

By the way, does anyone know what the Atari arcade game people have
against DEC? I am refering to the game _Major Havoc_, where one fights
against the Evil Vaxxxian Empire, from the planet of Maynard.

One trick that works on a lot of machines is to set the speed to the
lowest it will go, and send a null (usually control-@). I don't know
about the ST, since I don't have access to one.

I read an article in _The New York Times Today_, which confirmed my
suspicions that either Commodore or Atari will die after January or so.
Atari definitely appears to have the edge- a "cheaper," "faster," machine
with "better graphics" - or so they'd have us think.

But I saw lines like this in the "side - by - side comparison" charts in
some publications:

```
          ATARI 520 ST ................    COMMODORE AMIGA

     Colors:    512                      (Yes)
        Resolution
  (non-interlaced) mono: 640x400           640x200
```

Come on. That's plain misleading advertising.

Definitely going to be a lot of mudslinging this Christmas around Silicon
Valley and Pennsylvania.. (:-)

Who said there was a war? Both machines have a lot to contibute to the personal computer world. That aside, software at a show and software on the shelves are two vastly different things. I am certain that if Commodore had gone to the show they could have dug up at least two dozen software vendors to come to the show and display their wares, even if the software is not ready to ship. Electronic Arts, one of the biggest manufacturers of entertainment software, just last week started shipping Amiga software. To the best of my knowledge they are not even planning to produce on software for the ST. To claim that the software is here based on a few software vendors at a show is over-exagerating a little.

> So Atari follows in IBM's footsteps, and succeeds with a technically
> inferior product :-).

I still do not understand what people think technically superior is.
Obviously if price is not part of technical achievment then I will take
a Vme based Sun-3 anyday! It seems that the ST is very close technically
and indeed for a lot of people better technically and at less than half the
cost. If all you want is a 68000 and monochrome graphics the ST has far more
going for it. This is a large market!! So if you want the animation and the
built-in sound and you want to pay for it then do so... I would rather have
the extra money to buy a synthesizer personally. (controllable from the
built-in MIDI port)

> Seriously, I don't own either machine. I'm probably going to be buying one

I believe that 2-meg memory expansion boards are in beta test for the ST.
These require no soldering. The price is far less than the TECMAR bullshit.

> Of course, the plaintiff cries from people trying to twiddle the mouse from
> C doesn't help the ST any.

I agree thhat the software enviroment so far is better but I will probably use
OS-9 anyway and then they both will be identical

> And I'm going to ignore the prospects of Commodore going under. I'll pick

??????

> Final thought: I'd be suprised if the ST doesn't outsell the Amiga, by 2:1
> or better. After all, I expect most people to look at them, see windows and
> two price tags (one roughly 1/2 the other), and buy the smaller price tag.

This could be reasonably intelligent behavior if you aren't looking for some
extraas that the Amiga has. I do not believe the majority of people really
care about amimation and fancy built-in sound, or Bus-oriented expandability.

Action is a fantastic programming language. It is similiar to Pascal and c. It runs under a cartridge environment having its own editor and compiler. The Action compiler is extremely fast. It can compile source code from memory, disk, or both. The compiled code is true 6502 machine language; not interpreted P-code like so many other "compilers".

The reason that Action-written programs must run in the cartridge environment is that all Action internal routines (i.e. Graphics, Print, Locate, etc.) are linked to the corresponding cartridge address for those routines. O.S.S. provides a *Non-Commercial Run-Time Library* that is simply the source code for each of the Action internal routines. Compiling your program with the Run-Time Library *included* will produce object code that will execute in the Atari native environment without need of the Action cartridge. The Non-Commercial Run-Time Library can only be obtained by directly contacting OSS. (approx. $30.00 on last check). With the Run-Time Library, you can write Action programs and "give" them to your friends or distribute in the Public Domain. P.D. is a pre-condition OSS places on the Non-commercial Run-Time Library. For developers wishing to market Action based software, OSS has a Commercial Run-Time Library License available.

The Action cartridge supports integer arithmetic having single byte and double byte, signed and unsigned, variable types. The Action cartridge does NOT support REAL variable types. This is a real BOO! (or should I say an integer BOO!!). To compensate, OSS offers an Action Tool-Kit ($19 from Software Discounters of America,Antic 1/86). The Tool-Kit has, among other things, a set of routines supporting REAL variable types. The routines merely provide the hooks into the Atari OS to perform real number computations. They do not constitute a differing representation or implementation of real numbers. As such, they are a definite *kluge*. For example, one cannot say:

```
CIRC = DIAM * 3.14159
```

One has to say: (syntax may not be perfect)

```
RealAssign("3.14159",rpi)
RealMult(DIAM,rpi,CIRC)
```

Obviously, one cannot readily compute complex equations in this manner.

Action does support a great RECORD and POINTER implementation. Almost anything that can be done in Pascal or C with pointers can be done in Action. A bit of a warning, pointers can go flying off into never-never land since Action has no bounds checking.

I purchased my Action system (cartridge, tool-kit, and run-time library) about a year ago. Since then, my Atari has become a NEW machine. Previous to this purchase, I had not so much as turned-on my Atari for over 2 years. I had been bored by the slowness of Basic, and frustrated by the tedium of assembly. Action solves both problems

-- Bob Burch

P.S. A Basic program randomly displaying 1,000 asterisks in Gr.0 takes about 2 minutes to display. With Action the same program takes 7 seconds.

Lines: 86

I've been working on expanding my 800XL to 256K as per the BYTE article. I initially encountered trouble with the implementation and presumed that the problem was in software (ATARIRAM.ASM from BYTEnet). Much to my dismay and eventual glee, I discovered that the shielding of the XL had grounded the circuit causing partial operation. With this corrected the 256K XL expansion became operable. Therefore, the 9/85 BYTE article "The Quarter-Meg Atari", with supporting software, by Claus Buchholz does indeed work as published.

I wish to take this oppurtunity to thank all those individuals, contributing to this net, for providing the insight and encouragement necessary to have allowed me to continue this endeavor.

The BYTE implementation swaps 8 32K banks by manipulating PORTB bits 4, 5, and 6. The software provided will format a single virtual disk device D3: or D4: as a single or double density device depending on the options selected while assembling. The software will format the device to a full 720 sectors. Copying whole disks to the Ramdisk device is incredibly fast during the Ramdisk access phases. (I've configured a special version that uses two single density virtual devices. Copying between them is breath-taking.)

Disadvantages: First, the 8 32K segments are not 130XE compatible. Second, any interrupt encountered by a user program while the primary bank (0-$7FFF) is swapped out will cause a crash.

Short of being a great Ram-Disk application, the BYTE implementation leaves a lot to be desired. However, it is by no means a "dog" as it has been referred. If all you want is RamDisk, some inexpensive electronics project to play around with, and desire a do-able challenge; I fully recommend the Project as described in BYTE. (by the way, I wield a soldering-iron as a lumberjack would a scalpel).

There are alternatives, however. Some information I received from a friend,having access to CompuServe, I am passing along in another posting.

The first, by John P. Radigan, describes RamDisk controllers (ERAMDSK1 and ERAMDSK2) for the 9/85 BYTE circuit. These controllers work with DOS 2.0, DOS 2.5, DOS XL, and SmartDOS (I typically use SmartDOS).
The
controllers are "object" modules that can be obtained thru CompuServe. (Didn't I see something about BINHEX on this net, recently?)

The second is a 130XE compatible upgrade to the original circuit by Claus Buchholz himself. This article modifies the original circuit to provide complete compatibility. The controller associated with it is QMEGXLD.SRC. (I do not have a copy of this code. If anyone could obtain it, particular Michigan netters in 517, I would appreciate a posting either to this net or net.sources.)

Third, the Madison Area Atari Users Group (MAAUG) has a third version called RAMBO-XL (256K) as well as Terminator-XL (512K). These work and have been demonstrated according to their Newsletter. MAAUG offers pre-printed circuited boards (un-drilled) for a token sum. (I've ordered 5 boards for my User's Group and am awaiting delivery). Anyone interested should write (preferrably thru a User's Group) to:

MAAUG
P.O. Box 56191
Madison, WI 53705

Ask for a copy of the Oct. and Nov. Newsletters ($5.00 should get some circuit boards, I cannot speak for their production costs.)

Fourth, fellow netter C. David Young has been kind enough to pass along the information on his 256KXL. He offers a hardware kit (board assembled) for $99.95. I've seen this in a local store. It looks good, easy to

install, but the one I saw did not include software. This kit seems very complete, however, you still have to be somewhat adventuresome to summon up the courage to dismantle your XL. No sweat! The kit can be purchased from:

      CDY Consulting
      421 Hanbee
      Richardson, TX 75080
      (214) 235-2146

   Other products include: OMNIVIEW, OMNIMON, RAMROD, etc.

   The Buchholz 2nd upgrade, the MAAUG upgrade, and the CDY upgrade all use the same address scheme to switch 12 16k banks in $4000 - $7FFF using bits 2,3,5,6 of PORTB. None are truly 100% compatible with the 130XE, yet they are not really incompatible either. They merely extend bank switching capability beyond that defined by Atari. All implementations are compatible with each other, with the exception of the original BYTE implementation.

The following article has been passed down from CompuServe. It applies to the original circuit described in "The Quarter-Meg Atari" by Claus Buchholz in BYTE of 9/85.
==========

              256k 800XL Ram Disk Controller

                   Vers. 1.0   10/29/85

This is an enhanced version of the original Ram Disk Controller for a 256k 800XL as described by Claus Buchholz in his construction article which appeared in the Sept. '85 issue of BYTE magazine, pg. 247. Added is the capability to change the density of the ram-disk with multiple density DOS systems. This is accomplished via the PERCOM config block standard. Information on this subject can be found in the Oct. '85 issue of COMPUTE! magazine, pg.110. Many thanks to Bill Wilkinson for writing that article, without which, this function would not have been possible. The other major additon to this controller is the use of another drive while in single density mode. This gives the user the same amount of ram-disk storage regardless of which density is active. I have also included some primitive diagnostic routines that check the operation of the ram upgrade. Also, a hook has been added to the immediate vertical blank routine that will enable the HELP key to 'cold-boot' the computer without turning it off, toggle sound output for ram-disk access and a toggle to modify screen and characther color for compatability with monochrome monitors.

1). - Density default and changing density.

There are two versions of this controller, ERAMDSK1 and ERAMDSK2, they differ only in the default density setting when the system is first loaded. The drives recognized are D3: and D4:, the latter active only when single density is selected. Changing densities requires one precaution if you are switching from single to double density. Do not change D3:, use D4: instead. This will prevent a fatal I/O error from occuring if the DOS your using lists the state of all drives after one is changed as is the case with the CONFIG command in DOS XL. If that is the case, D4: will appear to be active but, if you list the active drive table again, D4: will then be inactive.

2). - Format and diagnostic routines.

Initialization of the drives takes a little longer now that a ram test has been included to check the memory in each of the 6 banks, (0-5), that comprise the ram-disk. I have also included a check for the bank select logic circuit. At the end of the ram test for each bank, the location $00FD is written with the number of the bank in use. When the ram-test phase has concluded, a loop check of the same address in each bank is performed to verify that 6 distinct banks exist. If a format error is returned during an initialize command, address $CC06 will contain the type of error that occured. Locations $CC00 through $CC05 hold the results of the error as follows:

```
$CC06 =  0 - No errors, operational.
     1 - Ram test failure.
     2 - Select logic error.

Ram test failure results:       Select logic results:
  ==========================          ======================
$CC00 - Bank # of bad address.       $CC00 - 00  ( Bank 0 )
$CC01 - Page # of bad address.       $CC01 - 01  ( Bank 1 )
$CC02 - Address in page.        $CC02 - 02  ( Bank 2 )
$CC03 - Data expected.          $CC03 - 03  ( Bank 3 )
$CC04 - Data received.          $CC04 - 04  ( Bank 4 )
```

If you have a select logic problem you will most likely see some sort of symmetry with the data in $CC00 through $CC05, for example, 00 00 02 02 04 04 would indicate a problem that results in the least significant bit of the bank select circuit not being set.

A problem with the ram test is not as hard to solve as the select logic. Not to say that there isn't a multitude of things that can go wrong with dynamic ram. But please take note that this ram test is only capable of finding a simple failure, not intermittent or other bizzare malfunctions. Also, only the first error encountered will be recorded before exiting the format routine. If there are multiple errors they will only show up after the first error has been corrected. The two types of failures that most often occur are either total chip failure (dead row or column) or one dead bit. The first failure would almost certainly prevent the computer from successfully completing a boot procedure, swapping one ram chip at a time and booting will usualy locate the offending chip unless two or more chips are faulty (mail order rejects). This test is centered on the second common error, to find the bad chip in this case is a straight forward process. Compare $CC03 and $CC04 to determine the bad bit, change the ram chip according to the following table:

```
Bit 0 - Chip U09 (closest to power switch)
 "  1 -   "  U10
 "  2 -   "  U11
 "  3 -   "  U12
 "  7 -   "  U16
 "  6 -   "  U15
 "  5 -   "  U14
 "  4 -   "  U13 (furthest from power switch)
```

3). - HELP key functions.

There are three functions that are controlled by the HELP, SHIFT and CONTROL keys as follows:

```
      <help> - toggle screen modifiers.
<shift> <help> - toggle ram-disk access sound.
 <control> <help> - perform cold boot.
```

The screen modifiers update the values of character lumenence, background and border colors and left cursor once every vertical blank. This is included as a convienence to users of monochrome monitors so the intensity and contrast controls don't have to be continualy changed between programs. The left margin is also set to 0 when this toggle is active. The sound toggle gives an audible appreciation of the speed of ram-disk use. The cold boot has been included be-

cause the reset hook can be stepped on when a lock-up or other sort of problem occurs. This way, the data in the ram-disk will not be destroyed because the computer doesn't have to be turned off in order to cold boot the system. I am fairly confident that this hook will not be disabled during operation, but, if you do experience something strange try to leave me a detailed account of what went wrong so that I can prevent it from occuring again. One final note about the cold boot, the burst of broken horizontal lines that appear for a short time when the system is first turned on will not show when a keyboard cold boot is initiated.

I have used this controller with DOS XL, DOS 2.0 and DOS 2.5 with no problems at all. I use Amodem 4.89 for telecommunications with two Indus GT disk drives running under DOS 2.5, and except for an occasional lock-up with the capture buffer when Atari translation is in use, I've never had a problem, typical time for a full buffer (22K+ bytes) to dump to a single density ram-disk takes only 25 seconds!

I can't comment on any other DOS systems, you have to find out just what is and isn't compatible. If you have any suggestions, please leave me a message via EASYPLEX, I'm not able to get to read the forum message base often enough.

John P. Radigan
(76545,201)

Of note to DOS XL 2.3xx users:
INIT.COM has a bug that doesn't let you initialize D4:, to correct this you need a sector editor. On a single density disk with INIT.COM on it, examine sector 2 of the file, byte 4 should be a $35 not $34, change and save the sector and INIT.COM will now work.

The two files DOSXL.SUP and DOSXL.XL are extended memory configurations that gives the user additional free memory. Do not, at any time, use DOSXL.XL, it will not work with this controller. DOSXL.SUP will work fine with DOS XL 2.30 and this ram-disk, but, DOSXL.SUP will not work with DOS XL 2.35i.

For users with Indus drives and synchromesh, please note that DUPDSK.COM and DUPDBL.COM while functional, have a rather obscure bug that turns off Synchromesh after writing to the ram-disk the first time. Synchromesh will re-activate at the end of the duplication. I contacted Indus but they feel that this is a trivial bug that probably won't be corrected because it only happens when a non-Indus drive is the destination. I have found that COPY Dn:*.* Dn:*.* is actually faster in this instance.

Finnaly, by copying all your .COM files to the ram-disk and changing your default drive to the ram-disk you will see that extended commands such as COPY are now painless. MAC65.COM for example, loads in under 4 seconds. A double density drive would take 11 secondes with synchromesh engaged to load, 22 seconds without synchromesh engaged.

This article has been passed down from CompuServe. It is a modification of the original circuit appearing in "The Quarter-Meg Atari" by Claus Buchholz in BYTE of 9/85.

==========

A 130XE-COMPATIBLE 256K UPGRADE FOR THE ATARI 800XL

by Claus Buchholz

I designed the 256K upgrade described in my article, "The Quarter-Meg Atari" (BYTE, September, 1985), in December, 1984. Since this predated the 130XE, there was no precedent for extended memory on the XLs. I felt free to implement a system of eight 32K banks. The major reason was to keep the add-on circuit as simple as possible.

The 130XE, introduced in early 1985, set a different standard for bank-select memory. It uses 16K banks and makes them separately available to both the CPU and the video controller (ANTIC). The XE has 128K total memory.
The 64K extended RAM is split into four 16K banks.

A 256K 800XL has 192K extended RAM, which requires 12 16K banks. I have designed a new upgrade for the 800XL that implements such a scheme. Its similarity to the 130XE's scheme allows use of software for the XE on a 256K 800XL.

To select one of four banks, the XE uses two bits, #2 and #3, in the memory control register (port B of the 6520 PIA, addressed at $D301 or 54017 decimal). Zeroing bit #4 makes the selected bank appear at addresses $4000-$7FFF (16384 to 32767 decimal), as seen by the CPU. Zeroing bit #5 makes it appear there as seen by ANTIC.

In my upgrade, bits #2, #3, #5 and #6 select one of the twelve banks.

Zeroing bit #4 makes the selected bank appear at $4000-$7FFF to both the CPU and ANTIC. So, any program for the XE that uses the extended RAM for CPU storage will work on an 800XL with this mod. Those programs won't use the additional 128K, though. Programs that use the video banking feature of the XE might run on the modified XL, but the screen display will be wrong.

The procedure for this upgrade is basically the same as in the article, except for the following points. If your ANTIC (U7) part number is CO21697, use the circuit described by the first connection list below. If it is CO12296, include the circuit in the second list. The circuit requires five connections to the PIA (U23). So, pins 12 through 16 must be bent up and connected to the circuit. The rest of the procedure is the same. Notice that this circuit has one more chip than the article's circuit. This is the price of compatibility.

With the 256K dynamic RAMs in your XL, be sure to wait at least ten seconds after turning the computer off. Otherwise it may not coldstart properly when you turn it back on.

My original RAMdisk software doesn't work with this new mod, so I have written a new version. It is used in the same way, except that it offers a choice of either two single-density RAMdisks or one double-density. If you wish a disk copy of the source and object code, send me a blank disk and return mailer with full postage, and I will promptly send it back with the software. Alternately, you may download the software from the Capitol Hill Atari Owners' Society BBS at 517-371-1106 or from the Castle Communications board at 517-371-4234. The source file is called QMEGXLD.SRC for Quater-MEG XL Double.

Also available is a RAMdisk program that sets up one single-density RAMdisk and leaves the XE-equivalent banks free for XE software. This is quite useful with BASIC XE, DOS 2.5, or the new Synapse software. Its name is QMEGXLS.SRC.

I ask one thing in return for this information: Please pass it around to all your interested friends. Put it in your club's library or on your favorite BBS. Encouraging software support of 256K will result in many interesting uses for it. Thank you and enjoy!

DEFINITION OF MEMORY CONTROL REGISTER AT $D301 (54017 DECIMAL)

XL MOD								130XE							
bit:	7	6	5	4	3	2	1	0	bit:	7	6	5	4	3	2	1	0
	D	a	b	E	c	d	B	R		D		V	C	x	y	B	R

D=0 enables diagnostic ROM
B=0 enables BASIC ROM
R=1 enables OS ROM
E=0 enables extended RAM
abcd is 4-bit extended RAM bank #
- ranges from 4 to 15
- banks 12 to 15 are equivalent to XE's banks 0 to 3

D=0 enables diagnostic ROM
B=0 enables BASIC ROM
R=1 enables OS ROM
V=0 enables extended RAM for video
C=0 enables extended RAM for CPU
xy is 2-bit extended RAM bank #
- ranges from 0 to 3

PARTS LIST

8 41256 256K-bit dynamic RAM (200ns or less)
1 74LS153 Dual 4-to-1 multiplexer (IC2)
1 74LS139 Dual 2-to-4 decoder (IC3)
1 - 33 ohm, 1/4 watt resistor

ADDITIONAL PARTS FOR ANTIC #CO12296

1 74LS158 Quad inverting 2-to-1 multiplexer (IC4)
1 74LS393 Dual 4-bit counter (IC5)

LIST OF CONNECTIONS FOR THE UPGRADE CIRCUIT

Instead of a drawing of the upgrade circuit, below is a list of connections. Each entry in the list begins with the name of the signal followed by all the IC pins that connect together and share the signal.
IC3-13 means pin 13 of IC3. The IC numbers appear in the parts list above. IC1 is the 74LS158 chip from socket U27 on the XL motherboard. DIP is the DIP header to be plugged into socket U27. U23-xx refers to the pins you bend up on the PIA chip at U23 on the motherboard.

Vcc : DIP-16, IC1-16, IC2-16, IC3-16, IC3-13
Vss : DIP-8, IC1-8, IC2-8, IC2-1, IC2-15, IC3-8
A7 : DIP-11, IC2-10, IC2-11
A15 : DIP-10, IC2-13, IC3-3
A6 : DIP-14, IC2-6, IC2-5
A14 : DIP-13, IC2-3, IC3-2
MUX : DIP-1, IC1-1, IC2-2
A4 : DIP-2, IC1-2
A12 : DIP-3, IC1-3
RA4 : IC1-4, DIP-4
A5 : DIP-5, IC1-5
A13 : DIP-6, IC1-6
RA5 : IC1-7, DIP-7
-E : DIP-15, IC1-15
RA7 : IC2-9, DIP-9

```
      RA6  : IC2-7, DIP-12
      PB2  : U23-12, IC2-4
      PB3  : U23-13, IC2-12
      PB4  : U23-14, IC3-1
      PB5  : U23-15, IC1-10
      PB6  : U23-16, IC1-11
      -Zd  : IC1-9, IC3-14
      -O1a : IC3-5, IC3-15, IC2-14
      -O2b : IC3-10, One side of resistor
      RA8  : Other side of resistor, Pin 1 of all RAMs

      If your U7 part number is CO12296, do not connect signal
    A7  above,  and
 make the following additional connections.  The  connection  to  U7  is  to  a
 trace on the motherboard that runs from pin 8 of U7.

      Vcc  : DIP-16, IC4-16, IC5-14, IC4-3
      Vss  : DIP-8, IC4-8, IC4-2, IC4-15, IC5-7, IC5-2, IC5-12
      A7   : DIP-11, IC4-6
      -REF : U7-8, IC4-1
      REF  : IC4-4, IC5-1
      A7'  : IC4-7, IC2-10, IC2-11
      Q7   : IC5-8, IC4-5
      Q3   : IC5-6, IC5-13

Summary: Yes, you've missed OS-9

Here we go again. Would you believe that there are no less than *2* 68K boards available for the IBM-PC. One of which costs about $1000.00. This is by Hallock Computer Systems. The other was, I think TLS. Both run OS-9 68K. I think I told you about OS-9 systems before and you said you wanted to develop in C (or was it someone else?), well, the C compiler for OS-9 probably costs about $100.00 and OS-9 code *is* ROMable.

Now, back to Atari :-)!

Cheers! -- Jim O.

> would like to hear real information about the two machines. So far, the
> main differences appear to be:
>
> (a) the ST is half the price of the AMIGA.

Approximately true. Depends on whether you want color or not.

> (b) the AMIGA has better special-purpose graphics capabilities than the
> ST, but at the expense of main CPU speed.

Absolutely false. The graphics capability is achieved with co-processors which tend to let the CPU run at full speed much more often than if the CPU were responsible for display updates. Note that the coprocessors also allow I/O to proceed independently of the CPU, as well.

> (c) the AMIGA graphics is said to be not usable at a
> resolution of 640x400 for text or serious graphics applications.

Probably true, but only until monitors become available that address the special problems with 640 X 400 mode (using color - there are monochrome monitors which will work quite well at 640 X 400, and the ST, as I understand it, forces monochrome at that resolution anyway)

> (d) the AMIGA is said to be more expandable than the ST.

Yes. The AMIGA has the system bus available on a connector on the side of the machine, and expansion cards are already becoming available.

> (e) the AMIGA has a multitasking operating system. Definitely a big plus,
> but as soon as OS9 is available for either machine, this does not
> matter anymore.

Perhaps, perhaps not. The Amiga's OS (NOT the AmigaDOS, but the underlying kernal) was specifically designed to take advantage of the large amount of intelligence held in the coprocessors. Unless the OS9 implementation is done VERY well, it probably will lose in efficiency. Note that OS9 was probably not designed for a high-power graphics environment, and Amiga's EXEC was.

'Twas the Night Before Start-up

'Twas the night before start-up and all through the net,
  not a packet was moving; no bit nor octet.
The engineers rattled their cards in despair,
  hoping a bad chip would blow with a flare.
The salesmen were nestled all snug in their beds,
  while visions of data nets danced in their heads.
And I with my datascope tracings and dumps
  prepared for some pretty bad bruises and lumps.
When out in the hall there arose such a clatter,
  I sprang from my desk to see what was the matter.

There stood at the threshold with PC in tow,
  An ARPANET hacker, all ready to go.
I could see from the creases that covered his brow,
  he'd conquer the crisis confronting him now.
More rapid than eagles, he checked each alarm
  and scrutinized each for its potential harm.

On LAPB, on OSI, X.25!
  TCP, SNA, V.35!

His eyes were afire with the strength of his gaze;
  no bug could hide long; not for hours or days.
A wink of his eye and a twitch of his head,
  soon gave me to know I had little to dread.
He spoke not a word, but went straight to his work,
  fixing a net that had gone plumb berserk;
And laying a finger on one suspect line,
  he entered a patch and the net came up fine!

The packets flowed neatly and protocols matched;
  the hosts interfaced and shift-registers latched.
He tested the system from Gateway to PAD;
  not one bit was dropped; no checksum was bad.
At last he was finished and wearily sighed
  and turned to explain why the system had died.
I twisted my fingers and counted to ten;

an off-by-one index had done it again...

I just purchased a sealed copy of Pinball
Construction set and cannot get it to boot
on my Atari 800xl. If I boot normally
(just insert disk and turn computer on) I get:

REMOVE CARTRIDGE

If I hold down the option key while booting I
get the Electronics Arts logo on the screen
then the whole thing goes blank and dies.

Do I have a defective disk or is there something
I am not aware of that I have to do to get this
booted.

Thanks

There has been mention on the net recently of the difficulty of using kermit through a TAC. The problem can be circumvented by disabling the interception of the `@' character. Of course, this disables the (re)programming of the TAC port until you log out and log back onto the TAC. The procedure is

@b i s
@b o s

These two commands to the TAC request binary input and output to the port, thus preventing the interception of any characters as special characters.

Steve Segletes
U.S. Army Ballistic Research Laboratory
Aberdeen Proving Ground, MD 21005-5066

<steven@brl.arpa>

p.s. the order in which the two commands are issued is important. Using the wrong order will result in the second command being passed through to the host system. It is possible that I have specified the wrong order above (I haven't used this feature in a while), but it should be immediately obvious if I did.

One reason that these comparisons are so silly is that the perspective of most of the people who write these "mine is superior articles" is limited. Atari early on targeted the European market and in the first year seemingly did not care a fig about the USA. However they have managed to capture the Europeans, and there is 10 times more software over there for the Atari than here for the Amiga. I like the Amiga, I really do (after all its just a computer), but these comparisons seem to all be Amiga people saying the Amiga is better and the atari people saying that they like their computers just fine. And the price!! (not to mention the faster benchmarks)

After owning an ST (paid $659 for B/W - mail order) for over 2 months now, I must admit that I'am really *very* pleased with it. My current use for the ST is as a terminal (PC/Inter Comm - very good VT emulation) accessing our VAX systems at work. The ST's monochrome 70Hz display must be one of the best displays around for software development (easy on the eyes).

Since I just mentioned the topic of software development, there are a few questions I have for anyone out there in netland regarding the ST and software development.

o When will TDI's Modula-2 development software begin to ship?

o Is there a standalone editor available now or becoming available in the near future for the ST, other then the Development System's MicroEmacs? In the PC world there are many editors to choose from (ie.Vedit,Brief,Pmate), when do you think editors of their abilities and functionality will begin to appear?

o Is there an ST version of DEC's EDT editor existing or being worked on now? The availability of a reconfigurable editor could help out here.

o As I mentioned above the terminal emulator package I now use is PC/Inter Comm, which does a very good job, however what would really come in handy is an emulator which runs in the GEM window environment and allows the user to switch context between say a dialed-up VAX in the background (80 col.) and a sizable, scrollable GEM window in the foreground (ST development environment), similar to MACterm.

Has anyone heard of something similar to this being worked on, or maybe even available now?

As for all this ST vs Amiga talk, well I wish both companies the best of luck on their decision to turn away from the "me-too" PC clone path and take that next step in advancing the state of the art in micro computing.....I've seen the future and it is bit mapped...

Mike Boiko

Summary: Amiga interleaves its bus access

In article <382@pedsgd.UUCP> bobh@pedsgd.UUCP (Bob Halloran) writes:
>Granted, the graphics chips relieve the 68000 from dealing with the
>display, as it must in the Mac, but the 68000 and the various co-processors
>must still contend for access to memory. YES, I/O can proceed independently,
>etc., but only ONE of the processors can use memory at a time. This
>HAS to impact the throughput of the 68000.

This is true. But don't forget that the Amiga interleaves its access
to the bus, using every available cycle, even the odd ones, whenever
possible. All of the DMA, including the display processors, use the
odd cycles. This enormously cuts down the contention for the bus.
The result of this is that the 68000 and other co-processors get to run
at full speed regardless of display processing. Only when the
display gets elaborate -- 640 across (either interlaced or not) and
4 bit-planes (16 colors onscreen) -- is there a significant lag
in CPU performance.
    The same goes for the other DMA devices: sprite, disk, and audio.
With a simple display, a few sprites and some simple tones playing,
you can fill a disk buffer and still have truly minimal interference
with the performance of the 68000.

Oh, come now, shall we resort to name-calling to achieve a logical end
to this? Commodore is in serious financial trouble. Period.

>On software availability:
>
>Lets see now. 520ST's became available in June and the software is now

Uh, excuse me, but the Amiga was launched on July 23, 1985 --

>us all know where the relative priorities of software producers lie. I

You know it's funny that you mention that now that Island Graphics has
dropped the Amiga (which Commodore can't afford it seems). The thing I
have seen of software availability is that there is *alot* of software
available for the ST. Commodore admittedly has said that the software
is lacking. Seems Comdex cleared up the issue of software -- for the ST
anyway.

>think it is easier to write programs for the Amiga and I think the designers
>think so too. I think good hardware design and good system software will beat
>early-to-market. I think no amount of partisanship by atari owners will

It seems that if you think anymore, you may just overuse the word. Is
there ever a time when you do more than *think*? Do you ever *do* anything?
Hmmm...

>... and I think its place in the market
>is secure for awhile at least. But I don't tkink the Amiga is going away.

There you go *thinking* again. Anyway, all flaming aside, I feel
a sense of jealousy here. It seems that people here have to justify
why they believe the Amiga is a better machine, because they can't
believe that a machine like the 520ST exists.

You know, it was interesting to read the article in Inforworld (12/2) on
"Christmas Contenders".

> "Observers have noted some clear distinctions between
> the Amiga buyer and the Atari 520ST buyer. Although
> the ST is the less expensive computer, its typical
> buyer is a veteran computer user, according to Martin
> Bartholomey, owner of Home Computers Co...
>
> "We're winning the battle of the techies," says Sam Tramiel
> president of Atari..."Hackers are our first customers.
> They influence the market and tell their friends."
> On the other hand, the current Amiga buyer is likely
> to be a first-time computer buyer, says Ed Anderson, vice
> president of marketing of The Computer Factory..."

The question then becomes: why do techies and experience computer
users prefer the 520ST over the higher-priced Amiga? Hmmm.

I probably planted a bomb. Oh well.

Aloha,

Summary: What's wrong with unbundled?

Bob, I don't see a problem here? If the prices are reasonable, then
what's wrong with selling the system unbundled? The question is whether
the total of the prices are much higher than the bundled prices. Even
then I think I'd prefer to buy in pieces if I could derive a benefit
that way. There *are* possible benefits too. I already have Shugart
standard disks and *many* monitors. All I'd need would be the CPU and
software. I'm not the only one in this position either. In fact
I'll bet there isn't more than 10% of all ST owners who didn't already
have at least 1 computer before they bought their ST.

                                        Cheers! -- Jim O.
